SQC

Problem input data frequently suffers from estimation error, and sometimes even very small errors can render the "optimal" solution irrelevant (e.g. seriously infeasible).

e.g. Pilot 4 from NETLIB : constraint 372

 $a^{T}x = -15.79081x_{826} - 8.598819x_{827} - 1.88789x_{828} - 1.362417x_{829}$

 $-1.526049x_{830} - 0.031883x_{849} - 28.725555x_{850} - 10.792065x_{851}$

 $-\,0.19004 x_{852}-2.757176 x_{853}-12.290832 x_{854}+717.562256 x_{855}$

 $-\,0.057865 x_{\!856}-3.785417 x_{\!857}-78.30661 x_{\!858}-122.163055 x_{\!859}$

 $- 6.46609x_{860} - 0.48371x_{861} - 0.615264x_{862} - 1.353783x_{863}$

 $-84.644257 x_{864} - 122.459045 x_{865} - 43.15593 x_{866} - 1.712592 x_{870}$

 $-0.401597 x_{871} + x_{880} - 0.946049 x_{898} - 0.946049 x_{916}$

 $\geq b = 23.387405$

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □

Problem input data frequently suffers from estimation error, and because of this the "optimal" solution computed is far from optimal in reality.

e.g. Computation of efficient frontier from mean-variance model

- True asset returns μ and covariance matrix Q
- Estimate asset returns $\hat{\mu}$ and covariance matrix \hat{Q}

$$\max_{x} \mu^{T} x - \lambda x^{T} Q x \quad \text{s.t.} \quad \mathbb{1}^{T} x = 1 \quad (Q P_{\lambda})$$

Family of true optimal portfolio { $x_{\lambda} : x_{\lambda}$ solves (QP_{λ}), $\lambda > 0$ } *True* efficient frontier : {($\sqrt{x_{\lambda}^{T}Qx_{\lambda}^{T}}, \mu^{T}x_{\lambda}$) : $\lambda > 0$ }

(\uparrow What you would have obtained *if* you knew the true parameters μ and *Q*.)

э

< ∃⇒

- Problem input data frequently suffers from estimation error.
- Solving an optimization problem based on nominal data alone could produce some "optimal solution" that is irrelevant in reality.
- Even if feasibility is not an issue, the "optimal" solution obtained is very likely far from optimal.

イロト イポト イヨト イヨト 二日

• Nominal LP problem:

$$\min_{x} \hat{c}^{T}x + \hat{d} \quad \text{s.t.} \quad \hat{A}x \leqslant \hat{b}$$

- Uncertain data (\hat{A}, \hat{b}) takes value in $\mathcal{U}_{A,b}$ (and (\hat{c}, \hat{d}) in $\mathcal{U}_{c,d}$)
- Robust counterpart:

 $\min_{x} \tilde{c}(x) \quad \text{s.t.} \quad Ax \leqslant b \quad \text{ for all } (A, b) \in \mathfrak{U}_{A, b}$

where $\tilde{c}(x) := \sup_{(c, d) \in \mathcal{U}_{c, d}} c^T x + d$.

- But what are the uncertainty sets?
- In finance, the uncertainty structure corresponds to the confidence region.
- So this problem is deterministic, but is a semi-infinite (and possibly non-smooth) programming problem!
- Infinite number of constraints poses computational difficulty.
- But constraints such as the last one can be dealt with efficiently.

イロト イポト イヨト イヨト 二日

Robust optimization: efficiency

An illustration in LP case:

• Consider an uncertain constraint

$$\hat{a}^T x \leqslant \hat{b} \quad \text{where } [\hat{a}; \hat{b}] = \left\{ [a^0; b^0] + \sum_{l=1}^L \zeta_l [a^l; b^l] : \|\zeta\|_2 \leqslant 1 \right\}$$

• Robust counterpart:

$$(a^0)^T x + \sum_{l=1}^L \zeta_l [a^l]^T x \leqslant b^0 + \sum_{l=1}^L \zeta_l b^l \quad \forall \, \|\zeta\|_2 \leqslant 1$$

SQC

Robust optimization: efficiency

An illustration in LP case:

• Consider an uncertain constraint

$$\hat{a}^T x \leqslant \hat{b}$$
 where $[\hat{a}; \hat{b}] = \left\{ [a^0; b^0] + \sum_{l=1}^L \zeta_l [a^l; b^l] : \|\zeta\|_2 \leqslant 1 \right\}$

• Robust counterpart:

$$\left\| ([\boldsymbol{a}^1]^T \boldsymbol{x} - \boldsymbol{b}^1, \dots, [\boldsymbol{a}^L]^T \boldsymbol{x} - \boldsymbol{b}^L)^T \right\|_2 \leqslant \boldsymbol{b}^0 - (\boldsymbol{a}^0)^T \boldsymbol{x}$$

which is not a "hard" constraint to deal with.

Vris Cheung (University of Waterloo)

2009 10 / 19

Robust optimization and efficiency

Robust optimization: efficiency

Robust counterparts of some classes of non-linear programming problems and LP with different uncertainty sets may have a finite representation, and can be solved efficiently.

 $(\lambda$ -)parametric QP

$$\max_{x} \mu^{T} x - \lambda x^{T} Q x \quad \text{s.t.} \quad \mathbb{1}^{T} x = 1$$

- where (assuming *n* stocks are available to choose)
- $x \in \mathbb{R}^n$: proportion of investment on the available assets
- $\mu \in \mathbb{R}^n$: expected return of the available assets
- $Q \in \mathbb{R}^{n \times n}$: covariance matrix of the available assets
 - $\lambda > 0$: risk aversion parameter

SQC

イロト イポト イヨト イヨト 一日

 (μ_0-) parametric QP

$$\min_{x} x^{T}Qx \quad \text{s.t.} \quad \mu^{T}x \geqslant \mu_{0} \text{ , } \mathbb{1}^{T}x = 1$$

- where (assuming *n* stocks are available to choose)
- $x \in \mathbb{R}^n$: proportion of investment on the available assets
- $\mu \in \mathbb{R}^n$: expected return of the available assets
- $Q \in \mathbb{R}^{n \times n}$: covariance matrix of the available assets
 - $\mu_0 \in \mathbb{R}$: minimum expected return guarantee

500

Uncertain (μ_0 -)parametric QP

$$\min_{x} x^{T} \hat{Q} x \quad \text{s.t.} \quad \hat{\mu}^{T} x \geqslant \mu_{0} \text{ , } \mathbb{1}^{T} x = 1$$

Robust counterpart

$$\min_{x} \left\{ \max_{Q \in \mathcal{U}_Q} x^T Q x : \ \mu^T x \geqslant \mu_0 \quad \forall \ \mu \in \mathcal{U}_\mu \text{ , } \ \mathbb{1}^T x = 1 \right\}$$

- \mathcal{U}_Q : uncertainty set for Q
- \mathcal{U}_{μ} : uncertainty set for μ

Vris Cheung (University of Waterloo)

2009 13/19

SQC

Robust counterpart:

$$\min_{x} \left\{ \max_{Q \in \mathcal{U}_{Q}} x^{T}Qx : \ \mu^{T}x \geqslant \mu_{0} \quad \forall \ \mu \in \mathcal{U}_{\mu} \ , \ \mathbb{1}^{T}x = 1 \right\}$$

Some special cases:

 $\circ Q$ is certain :

$$\begin{aligned} \mathcal{U}_{\mu} &= \{ \mu : \hat{\mu} - \delta \leqslant \mu \leqslant \hat{\mu} + \delta \} \\ \Longrightarrow \min_{x} x^{T} Q x \quad \text{s.t.} \quad \mu^{T} x - \delta^{T} |x| \geqslant \mu_{0} \text{, } \mathbb{1}^{T} x = 1 \end{aligned}$$

Vris Cheung (University of Waterloo)

ヘロト ヘロト ヘヨト ヘヨト

Sharpe ratio maximization

Nominal problem:

$$\max_{x} \frac{\hat{\mu}^{T} x - r_{f}}{\sqrt{x^{T} \hat{Q} x}} \quad \text{s.t.} \quad \mathbb{1}^{T} x = 1 \quad , \quad x \ge 0$$

Robust counterpart:

$$\max_{x} \ \left\{ \min_{\mu, \ Q} \ \frac{\mu^T x - r_f}{\sqrt{x^T Q x}} \quad \text{s.t.} \quad \mu \in \mathfrak{U}_{\mu} \text{ , } \ Q \in \mathfrak{U}_Q \right\} \quad \text{s.t. } \mathbb{1}^T x = 1 \quad \text{,} \quad x \geqslant 0$$

It can be shown that the above max-min problem can be reduced to a SOCP (with 2n + 6 variables and 8 constraints).

Vris Cheung (University of Waterloo)

2009 17/19

Sharpe ratio maximization

Advantages of robustification:

- Lower turnover [Ceira]
 - At 95% confidence level, turnover drops by 4%.
 - At 99% confidence level, turnover drops by 7%.
- This indicates a lower aggregate transaction cost.
- Higher terminal wealth [Goldfarb and Iyengar]
 - At 95% confidence level, final wealth is 40% higher.
 - At 99% confidence level, final wealth is 50% higher.

- Robust optimization can give uncertainty-immune solutions
- Many robust optimization problems can be solved efficiently
- $\circ~$ Robust optimization can producing "stable" solutions \implies lower turnover rate
 - \implies suitable for long term planning
