Sensor Network Localization, SNL

SNL, Special Case of EDMC?

- n ad hoc wireless sensors (nodes) to locate in \mathbb{R}^r ,
(r is embedding dimension;
sensors $p_i \in \mathbb{R}^r, i \in V := 1, \dots, n$)
- m of the sensors are anchors, $p_i, i = n - m + 1, \dots, n$)
(e.g. using GPS)
- pairwise distances known within radio range R ,
 $D_{ij} = \|p_i - p_j\|^2, ij \in E$

Current Techniques: Nearest, Weighted, SDP Approx.

$$\min_{Y \succeq 0, Y \in \Omega} \|H \circ (\mathcal{K}(Y) - D)\|$$

SDP program is: Expensive/low accuracy/implicitly highly degenerate (cliques restrict ranks of feasible Y s)

Applications

Tracking Humans/Animals/Equipment

- monitoring: natural habitat; earthquakes and volcanos; weather and ocean currents.
- military, tracking of goods, vehicle positions, surveillance, (where open-air positioning is not feasible), random deployment in inaccessible terrains or disaster relief operations

sensors everywhere - by 2084!

Lobster migration

Underlying Graph Realization/Partial EDM

Graph $\mathcal{G} = (\mathcal{V}, \mathcal{E}, \omega)$

- node set $\mathcal{V} = \{1, \dots, n\}$
- edge set $(i, j) \in \mathcal{E}$; $\omega_{ij} = \|p_i - p_j\|^2$ known approximately
- The anchors form a clique (complete subgraph)
- **Realization of \mathcal{G} in \mathbb{R}^r** : a mapping of node $v_i \rightarrow p_i \in \mathbb{R}^r$ with squared distances given by ω .

Corresponding Partial Euclidean Distance Matrix, EDM

$$D_{ij} = \begin{cases} d_{ij}^2 & \text{if } (i, j) \in \mathcal{E} \\ 0 & \text{otherwise,} \end{cases}$$

$d_{ij}^2 = \omega_{ij}$ are known squared Euclidean distances between sensors p_i, p_j ; anchors correspond to a **clique**.

Sensor Localization Problem/Partial EDM

Sensors and Anchors

SDP: Cone and Faces

S_+^k , Cone of SDP matrices in S^k

- inner product $\langle A, B \rangle = \text{trace } AB$
- Löwner (psd) partial order $A \succeq B, A \succ B$

Faces of cone K

- $F \subseteq K$ is a face of K , denoted $F \triangleleft K$, if
 $(x, y \in K, \frac{1}{2}(x+y) \in F) \implies (\text{cone}\{x, y\} \subseteq F)$.
- $F \triangleleft K$, if $F \triangleleft K, F \neq K$; F is proper face if $\{0\} \neq F \triangleleft K$.
- $F \triangleleft K$ is exposed if: intersection of K with a hyperplane.
- $\text{face}(S)$ denotes smallest face of K that contains set S .

Facial Structure of SDP Cone

S_+^k is a **Facially Exposed Cone**

All faces are exposed.

Faces of S_+^k Equivalence to **Subspaces of \mathbb{R}^k**

- face $F \trianglelefteq S_+^k$ is determined by **range of any**, $S \in \text{relint } F$,
i.e. let $S = U\Gamma U^T$ be compact spectral decomposition, with diagonal matrix of eigenvalues $\Gamma \in S_{++}^t$, then:

$$\boxed{F = US_+^t U^T} \quad (F \text{ associated with } \mathcal{R}(U))$$

- $\dim F = t(t+1)/2$.

Further Notation

Matrix with Fixed Principal Submatrix

For $Y \in \mathcal{S}^n$, $\alpha \subseteq \{1, \dots, n\}$: $Y[\alpha]$ denotes principal submatrix formed from rows & cols with indices α .

Sets with Fixed Principal Submatrices

If $|\alpha| = k$ and $\bar{Y} \in \mathcal{S}^k$, then:

$$\mathcal{S}^n(\alpha, \bar{Y}) := \{Y \in \mathcal{S}^n : Y[\alpha] = \bar{Y}\},$$

$$\mathcal{S}_+^n(\alpha, \bar{Y}) := \{Y \in \mathcal{S}_+^n : Y[\alpha] = \bar{Y}\}$$

i.e. the subset of matrices $Y \in \mathcal{S}^k$ ($Y \in \mathcal{S}_+^k$) with principal submatrix $Y[\alpha]$ fixed to \bar{Y} .

SNL Connection to SDP (Lin. Trans., Adjoint)

$$v = \text{diag}(S) \in \mathbb{R}^n, S = \text{Diag}(v) \in \mathcal{S}^n$$

$\text{diag} = \text{Diag}^*$ (adjoint)

for $B \in \mathcal{S}^n$, $\text{offDiag}(B) := B - \text{Diag}(\text{diag}(B))$

$$D = \mathcal{K}(B) \in \mathcal{E}^n, B = \mathcal{K}^\dagger(D) \in \mathcal{S}^n \cap \mathcal{S}_C$$

Let $P^T = [p_1 \ p_2 \ \dots \ p_n] \in \mathcal{M}^{r \times n}$;

$B := PP^T \in \mathcal{S}^n$; $D \in \mathcal{E}^n$ be corresponding EDM.

$$\begin{aligned} \text{(from } \mathcal{S}^n) \quad \mathcal{K}(B) &:= \mathcal{D}_e(B) - 2B \\ &:= \text{diag}(B) e^T + e \text{diag}(B)^T - 2B \\ &= \left(p_i^T p_i + p_j^T p_j - 2p_i^T p_j \right)_{i,j=1}^n \\ &= \left(\|p_i - p_j\|_2^2 \right)_{i,j=1}^n \\ &= D \quad \text{(to } \mathcal{E}^n). \end{aligned}$$

$$\mathcal{K} : \mathcal{S}_+^n \cap \mathcal{S}_C \rightarrow \mathcal{E}^n$$

Linear Transformations: $\mathcal{D}_v(B), \mathcal{K}(B), \mathcal{T}(D)$

- allow: $\mathcal{D}_v(B) := \text{diag}(B) v^T + v \text{diag}(B)^T$;
 $\mathcal{D}_v(y) := yv^T + vy^T$
- adjoint $\mathcal{K}^*(D) = 2(\text{Diag}(De) - D)$.
- \mathcal{K} is $1-1$, onto between **centered** and **hollow** subspaces:
 $\mathcal{S}_C := \{B \in \mathcal{S}^n : Be = 0\}$;
 $\mathcal{S}_H := \{D \in \mathcal{S}^n : \text{diag}(D) = 0\} = \mathcal{R}(\text{offDiag})$
- $J := I - \frac{1}{n}ee^T$ (orthogonal projection onto $M := \{e\}^\perp$);
- $\mathcal{T}(D) := -\frac{1}{2}J \text{offDiag}(D)J \quad (= \mathcal{K}^\dagger(D))$

Properties of Linear Transformations

$\mathcal{K}, \mathcal{T}, \text{Diag}, \mathcal{D}_e$

$$\mathcal{R}(\mathcal{K}) = \mathcal{S}_H; \quad \underline{\mathcal{N}(\mathcal{K}) = \mathcal{R}(\mathcal{D}_e)};$$

$$\mathcal{R}(\mathcal{K}^*) = \mathcal{R}(\mathcal{T}) = \mathcal{S}_C; \quad \mathcal{N}(\mathcal{K}^*) = \mathcal{N}(\mathcal{T}) = \mathcal{R}(\text{Diag});$$

$$\mathcal{S}^n = \mathcal{S}_H \oplus \mathcal{R}(\text{Diag}) = \mathcal{S}_C \oplus \mathcal{R}(\mathcal{D}_e).$$

$$\mathcal{T}(\mathcal{E}^n) = \mathcal{S}_+^n \cap \mathcal{S}_C \quad \text{and} \quad \mathcal{K}(\mathcal{S}_+^n \cap \mathcal{S}_C) = \mathcal{E}^n.$$

Rank minimization heuristics for the EDM completion problem

heuristic to encourage low rank solution of semidefinite relaxation, Weinberger, 2004

- try to **flatten the graph** associated with partial EDM ;
- push the nodes of the graph away from each other as much as possible;
- **analogy**: a loose string on the table can occupy two dimensions, but the same string pulled taut occupies just one dimension.

Low Rank

maximize the objective function

$$\sum_{i,j=1}^n \|p_i - p_j\|^2 = e^T \mathcal{K}(PP^T)e, \quad P := \begin{bmatrix} p_1^T \\ \vdots \\ p_n^T \end{bmatrix},$$

s.t. distance constraints holding.

Include centering $P^T e = 0$

$$\begin{aligned} e^T \mathcal{K}(PP^T)e &= \langle ee^T, \mathcal{K}(PP^T) \rangle = \langle \mathcal{K}^*(ee^T), PP^T \rangle = \\ &= \langle 2(\text{Diag}(ee^T e) - ee^T), PP^T \rangle = \langle 2(nI - ee^T), PP^T \rangle = \\ &= \langle 2nI, PP^T \rangle - \langle ee^T, PP^T \rangle = 2n \cdot \text{trace}(PP^T) \end{aligned}$$

and $\text{trace}(PP^T) = \sum_{i=1}^n \|p_i\|^2$

so, pushing nodes away from each other is equivalent to pushing nodes away from origin

Regularization

regularized semidefinite relaxation of the low-dimensional Euclidean distance matrix completion problem

assume points centered at origin; normalize by dividing by $2n$;
substitute $Y = PP^T$:

$$\begin{array}{ll} \text{maximize} & \text{trace}(Y) \\ \text{subject to} & H \circ \mathcal{K}(Y) = H \circ D \\ & Y \in \mathcal{S}_+^n \cap \mathcal{S}_C^n. \end{array}$$

Nuclear Norm Heuristic for Rank Minimization

nuclear norm of a matrix $X \in \mathbb{R}^{m \times n}$

$$\|X\|_* := \sum_{i=1}^k \sigma_i(X),$$

$\sigma_i(X)$ is i^{th} largest singular value of X , $\text{rank}(X) = k$.

nuclear norm of symmetric matrix $Y \in \mathcal{S}^n$ is

$$\|Y\|_* = \sum_{i=1}^n |\lambda_i(Y)|.$$

trace min vs max

numerical tests show min (max) yields high (low) rank
alternatively, try max log-det heuristic

Single Clique/Facial Reduction for SNL

$$\bar{D} \in \mathcal{E}^k, \alpha \subseteq 1:n, |\alpha| = k$$

Define $\mathcal{E}^n(\alpha, \bar{D}) := \{D \in \mathcal{E}^n : D[\alpha] = \bar{D}\}$.

Given \bar{D} ; find a corresponding $B \succeq 0$; find the corresponding face; find the corresponding subspace.

Basic Theorem for Single Clique/Facial Reduction

THEOREM 1: Single Clique Reduction

Let $\bar{D} := D[1:k] \in \mathcal{E}^k$, $k < n$, with embedding dimension $t \leq r$, and $B := \mathcal{K}^\dagger(\bar{D}) = \bar{U}_B S \bar{U}_B^T$, where $\bar{U}_B \in \mathcal{M}^{k \times t}$, $\bar{U}_B^T \bar{U}_B = I_t$, and $S \in \mathcal{S}_{++}^t$. Furthermore, let $U_B := \begin{bmatrix} \bar{U}_B & \frac{1}{\sqrt{k}} \mathbf{e} \end{bmatrix} \in \mathcal{M}^{k \times (t+1)}$, $U := \begin{bmatrix} U_B & 0 \\ 0 & I_{n-k} \end{bmatrix}$, and let $\begin{bmatrix} V & \frac{U^T \mathbf{e}}{\|U^T \mathbf{e}\|} \end{bmatrix} \in \mathcal{M}^{n-k+t+1}$ be orthogonal. Then:

$$\begin{aligned} \text{face } \mathcal{K}^\dagger(\mathcal{E}^n(1:k, \bar{D})) &= (US_+^{n-k+t+1}U^T) \cap \mathcal{S}_C \\ &= (UV)S_+^{n-k+t}(UV)^T \end{aligned}$$

Note that we add $\frac{1}{\sqrt{k}}\mathbf{e}$ to represent $\mathcal{N}(\mathcal{K})$; then we use V to eliminate \mathbf{e} to recover *centered* face.

Positive Integers for Intersecting Cliques

Two Intersection Sets, α_1, α_2 .

For each clique $|\alpha| = k$, we get a corresponding face/subspace ($k \times r$ matrix) representation. We now see how to handle two cliques, α_1, α_2 , that intersect.

Two (Intersecting) Clique Reduction/Subsp. Repres.

THEOREM 2: Clique Intersection Reduction/Subsp. Repres.

$$\begin{aligned} \alpha_1 &:= 1:(\bar{k}_1 + \bar{k}_2), & \alpha_2 &:= (\bar{k}_1 + 1):(\bar{k}_1 + \bar{k}_2 + \bar{k}_3) \subseteq 1:n, \\ k_1 &:= |\alpha_1| = \bar{k}_1 + \bar{k}_2, & k_2 &:= |\alpha_2| = \bar{k}_2 + \bar{k}_3, \\ k &:= \bar{k}_1 + \bar{k}_2 + \bar{k}_3. \end{aligned}$$

For $i = 1, 2$, let $\bar{D}_i := D[\alpha_i] \in \mathcal{E}^{k_i}$, with embedding dimension t_i , and $B_i := \mathcal{K}^\dagger(\bar{D}_i) = \bar{U}_i S_i \bar{U}_i^T$, where $\bar{U}_i \in \mathcal{M}^{k_i \times t_i}$, $\bar{U}_i^T \bar{U}_i = I_{t_i}$, and $S_i \in \mathcal{S}_{++}^{t_i}$. Furthermore, for $i = 1, 2$, let

$U_i := \begin{bmatrix} \bar{U}_i & \frac{1}{\sqrt{k_i}} \mathbf{e} \end{bmatrix} \in \mathcal{M}^{k_i \times (t_i+1)}$, and let $\bar{U} \in \mathcal{M}^{k \times (t+1)}$ satisfy

$$\mathcal{R}(\bar{U}) = \mathcal{R} \left(\begin{bmatrix} U_1 & 0 \\ 0 & I_{\bar{k}_3} \end{bmatrix} \right) \cap \mathcal{R} \left(\begin{bmatrix} I_{\bar{k}_1} & 0 \\ 0 & U_2 \end{bmatrix} \right), \text{ with } \bar{U}^T \bar{U} = I_{t+1}$$

cont. . .

Two (Intersecting) Clique Reduction, cont. . .

THEOREM 2 Nonsing. Clique Inters. cont. . .

cont. . . with

$$\mathcal{R}(\bar{U}) = \mathcal{R} \left(\begin{bmatrix} U_1 & 0 \\ 0 & I_{k_3} \end{bmatrix} \right) \cap \mathcal{R} \left(\begin{bmatrix} I_{k_1} & 0 \\ 0 & U_2 \end{bmatrix} \right), \text{ with } \bar{U}^T \bar{U} = I_{t+1},$$

let $U := \begin{bmatrix} \bar{U} & 0 \\ 0 & I_{n-k} \end{bmatrix} \in \mathcal{M}^{n \times (n-k+t+1)}$ and let

$\begin{bmatrix} V & \frac{U^T e}{\|U^T e\|} \end{bmatrix} \in \mathcal{M}^{n-k+t+1}$ be orthogonal. Then

$$\begin{aligned} \underline{\bigcap_{i=1}^2 \text{face } \mathcal{K}^\dagger(\mathcal{E}^n(\alpha_i, \bar{D}_i))} &= (US_+^{n-k+t+1}U^T) \cap \mathcal{S}_C \\ &= (UV)S_+^{n-k+t}(UV)^T \end{aligned}$$

Basic work: find \bar{U} to repres. inters. of 2 subspaces.

Two (Intersecting) Clique Reduction Figure

Completion: missing distances can be recovered if desired.

Two (Intersecting) Clique Explicit Completion

COR. Intersection with Embedding Dim. r /Completion

Hypotheses of Theorem 2 holds. Let $\bar{D}_i := D[\alpha_i] \in \mathcal{E}^{k_i}$, for $i = 1, 2$,

$\beta \subseteq \alpha_1 \cap \alpha_2, \gamma := \alpha_1 \cup \alpha_2, \bar{D} := D[\beta], B := \mathcal{K}^\dagger(\bar{D}), \bar{U}_\beta := \bar{U}(\beta, \cdot)$, where $\bar{U} \in \mathcal{M}^{k \times (t+1)}$ satisfies intersection equation of Theorem 2. Let $\begin{bmatrix} \bar{V} & \frac{\bar{U}^T e}{\|\bar{U}^T e\|} \end{bmatrix} \in \mathcal{M}^{t+1}$ be orthogonal. Let

$Z := (J\bar{U}_\beta \bar{V})^\dagger B (J\bar{U}_\beta \bar{V})^\dagger{}^T$. If the embedding dimension for \bar{D} is r , THEN $t = r$ in Theorem 2, and $Z \in \mathcal{S}_+^r$ is the unique solution of the equation $(J\bar{U}_\beta \bar{V})Z(J\bar{U}_\beta \bar{V})^T = B$, and the **exact completion** is

$$D[\gamma] = \mathcal{K} \left((\bar{U}\bar{V})Z(\bar{U}\bar{V})^T \right).$$

2 (Inters.) Clique Red. **Figure**/Singular Case

Two (Intersecting) Clique Reduction Figure/Singular Case

Use R as lower bound in singular/nonrigid case.

Two (Inters.) Clique Explicit Compl.; Sing. Case

COR. Clique-Sing.; Intersect. Embedding Dim. $r - 1$

Hypotheses of previous COR holds. For $i = 1, 2$, let $\beta \subset \delta_i \subseteq \alpha_i$, $A_i := J\bar{U}_{\delta_i}\bar{V}$, where $\bar{U}_{\delta_i} := \bar{U}(\delta_i, :)$, and $B_i := \mathcal{K}^\dagger(D[\delta_i])$. Let $\bar{Z} \in \mathcal{S}^t$ be a particular solution of the linear systems

$$\begin{aligned} A_1 Z A_1^T &= B_1 \\ A_2 Z A_2^T &= B_2. \end{aligned}$$

If the embedding dimension of $D[\delta_i]$ is r , for $i = 1, 2$, but the embedding dimension of $\bar{D} := D[\beta]$ is $r - 1$, then the following holds. cont. . .

2 (Inters.) Clique Expl. Compl.; Degen. cont. . .

COR. Clique-Degen. cont. . .

The following holds:

- 1 $\dim \mathcal{N}(A_i) = 1$, for $i = 1, 2$.
- 2 For $i = 1, 2$, let $n_i \in \mathcal{N}(A_i)$, $\|n_i\|_2 = 1$, and $\Delta Z := n_1 n_2^T + n_2 n_1^T$. Then, Z is a solution of the linear systems if and only if $Z = \bar{Z} + \tau \Delta Z$, for some $\tau \in \mathcal{R}$
- 3 There are at most two nonzero solutions, τ_1 and τ_2 , for the generalized eigenvalue problem $-\Delta Z v = \tau \bar{Z} v$, $v \neq 0$. Set $Z_i := \bar{Z} + \frac{1}{\tau_i} \Delta Z$, for $i = 1, 2$. Then the exact completion is one of $D[\gamma] \in \{\mathcal{K}(\bar{U} \bar{V} Z_i \bar{V}^T \bar{U}^T) : i = 1, 2\}$

Clique Initialization

LEMMA Clique Initialization (by triangle inequality)

For each $i \in \{1, \dots, n\}$, use half the radio range and define the set

$$C_i := \{j \in \{1, \dots, n\} : D_{ij} \leq (R/2)^2\}.$$

Then each C_i corresponds to a clique of sensors that are within radio range of each other.

Current Set of Cliques, $\{C_i\}_{i \in \mathcal{C}}$

indices $\mathcal{C} \subseteq \{1 : n\}$ corresponding to at most n cliques $\{C_i\}_{i \in \mathcal{C}}$.

Node Absorption

Clique C_i Absorbs Node j

Clique Absorption

COROLLARY Clique Absorption

Let C_k , for $k \in \mathcal{C}$, be a given clique with node $l \notin C_k$,
 $\beta := \{j_1, j_2, j_3\} \subseteq C_k$, and $\max_{i=1,2,3} D_{lj_i} \leq R^2$. If
$$\text{rank } \mathcal{K}^\dagger(D[\beta]) = r,$$

then l can be absorbed by the clique C_k ; and, we can complete the missing elements in column (row) l of $D[C_k \cup \{l\}]$.

COROLLARY Clique Absorption-Degenerate

Similar to the **degenerate case** for the intersection, we can **use the lower bound** and obtain clique absorption for the case that the embedding dimension is only $r - 1$.

Algorithm

Initialize

$$C_i := \{j : (D_p)_{ij} < (R/2)^2\}, \quad \text{for } i = 1, \dots, n$$

Iterate

- For $|C_i \cap C_j| \geq r + 1$, do Rigid Clique Union
- For $|C_i \cap \mathcal{N}(j)| \geq r + 1$, do Rigid Node Absorption
- For $|C_i \cap C_j| = r$, do Non-Rigid Clique Union (lower bnds)
- For $|C_i \cap \mathcal{N}(j)| = r$, do Non-Rigid Node Absorp. (lower bnds)

Finalize

When \exists a clique containing all anchors, use computed facial representation and positions of anchors to solve for X

Algorithm

Initialize

$$C_i := \{j : (D_p)_{ij} < (R/2)^2\}, \quad \text{for } i = 1, \dots, n$$

Iterate

- For $|C_i \cap C_j| \geq r + 1$, do **Rigid Clique Union**
- For $|C_i \cap \mathcal{N}(j)| \geq r + 1$, do **Rigid Node Absorption**
- For $|C_i \cap C_j| = r$, do **Non-Rigid Clique Union** (lower bnds)
- For $|C_i \cap \mathcal{N}(j)| = r$, do **Non-Rigid Node Absorp.** (lower bnds)

Finalize

When \exists a clique containing all **anchors**, use computed **facial representation** and **positions of anchors** to solve for X

Algorithm

Initialize

$$C_i := \{j : (D_p)_{ij} < (R/2)^2\}, \quad \text{for } i = 1, \dots, n$$

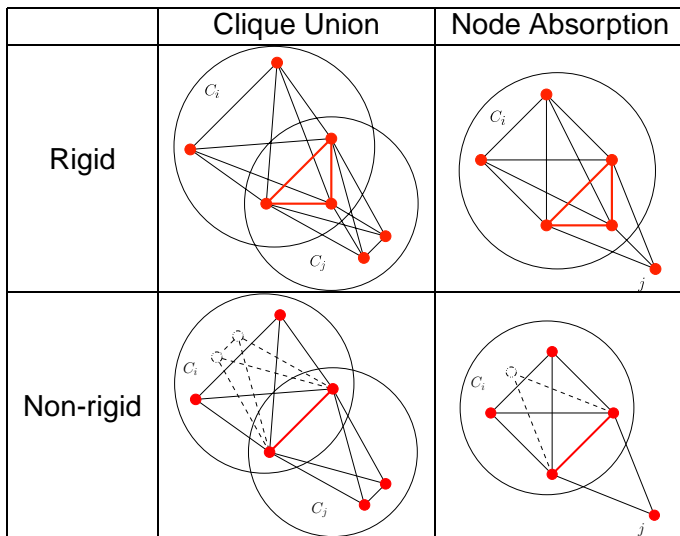

Iterate

- For $|C_i \cap C_j| \geq r + 1$, do **Rigid Clique Union**

EDM Completion Problem, EDMC

- given certain fixed elements of a EDM matrix A
- the other elements are unknown (free)
- complete this matrix to an EDM

$$\mathcal{S} = \{(i, j) : A_{i,j} = \frac{1}{\sqrt{2}}b_k \text{ is known, fixed, } i < j\}, \quad |\mathcal{S}| = m,$$

$$\begin{array}{ll}
 \text{(EDMC)} & \mu^* := \min_{X} f(X) := \frac{1}{2} \|X\|_F^2 \\
 & \text{subject to } \mathcal{A}(X) = b \\
 & X \succeq 0,
 \end{array}$$

constraint $\mathcal{A} = \mathcal{I} \cdot \mathcal{L} : \mathcal{S}^{n-1} \rightarrow \mathbb{R}^{|\mathcal{S}|}$ yields interpolation conditions

$$\mathcal{A}(X)_{ij} = \text{trace } E_{ij} \mathcal{L}(X) = b_k, \quad \forall k \cong (ij) \in \mathcal{S},$$

Duality/Optimality for EDMC

- strict convexity, coercivity implies compact level sets
- EDMC attained and no duality gap (actually primal and dual attainment)

Lagrangian dual

$$\mu^* = \nu^* := \max_{\Lambda \succeq 0, y \in \mathbb{R}^{|S|}} \min_X \frac{1}{2} \|X\|_F^2 + y^T (b - \mathcal{A}(X)) - \text{trace } \Lambda X$$

characterization of optimality

THEOREM Suppose that the feasible set of EDMC is not the empty set. Then the optimal solution of EDMC is $D = \mathcal{L}([\mathcal{A}^*(y)]_+)$, where y is the unique solution of the single equation

$$\mathcal{A}([\mathcal{A}^*(y)]_+) = b,$$

and B_+ denotes the projection of the symmetric matrix $B \in \mathcal{S}^{n-1}$ onto the cone \mathcal{P}_{n-1} .

Proof

optimality conditions after differentiation

$$\begin{array}{ll}
 X = \mathcal{A}^*(y) + \Lambda \succeq 0, & \Lambda \succeq 0, & \text{dual feasibility} \\
 \mathcal{A}(X) = b & & \text{primal feasibility} \\
 \Lambda X = 0 & & \text{complementary slackness}
 \end{array}$$

This means that $\mathcal{A}^*(y) = X - \Lambda$, where both $X \succeq 0, \Lambda \succeq 0$, and $\Lambda X = 0$. Therefore the three symmetric matrices

$W = \mathcal{A}^*(y), X, \Lambda$ are mutually diagonalizable. We write

$X = PD_X P^T, \Lambda = PD_\Lambda P^T$, i.e. we conclude that

$W = \mathcal{A}^*(y) = P(D_X - D_\Lambda)P^T, D_X D_\Lambda = 0$. Therefore

$[\mathcal{A}^*(y)]_+ = PD_X P^T = X$.

QED

Efficient/Explicit Solution if $y \geq 0$

large class (generic?) can be solved in polytime.

COROLLARY The linear operator \mathcal{A} is onto and $\mathcal{A}\mathcal{A}^*$ is nonsingular. Suppose that $y = (\mathcal{A}\mathcal{A}^*)^{-1}b \in \mathbb{R}_+^m$. Then

$$D = \mathcal{L}(\mathcal{A}^*(y))$$

is the unique solution of EDMC.

Proof: That \mathcal{A} is onto follows from the definitions.

If $y \geq 0$, then the matrix $\mathcal{I}(y) \geq 0$ with 0 diagonal. Therefore, $X = \mathcal{L}^*(\mathcal{I}(y))$ is diagonally dominant with nonnegative diagonal, i.e. $X \succeq 0$ by Gersgorin's disk theorem. This implies that D is a distance matrix and it satisfies the interpolation conditions, i.e. it satisfies the optimality conditions in the Theorem.

QED

Numerics: dim vs dens with # of failures in 100 tests

$y = \mathcal{A}^\dagger b \succeq 0$ may not hold in general, we still get a distance matrix D , i.e. $\mathcal{A}^*(y) \succeq 0$, $n = 10 : 10 : 100$; density $.1 : .1 : .8$.

$n \backslash$ density	.1	.2	.3	.4	.5	.6	.7	.8

100	0	0	0	0	1	6	5	5

Summary

- Many hard (combinatorial) problems can be **modelled** using quadratic objectives and constraints, **QQP**s.
- QQP's are generally NP-hard problems. **But**, the Lagrangian relaxation can be **solved efficiently** using the equivalent SDP (relaxation).
- The **special structure** of the SDP relaxations can be exploited in order to get efficient solutions for large scale problems.
- Many SDP relaxations of combinatorial problems are degenerate. **But**, this **degeneracy can be exploited**. In particular, the SDP relaxation of SNL is highly (implicitly) degenerate. This degeneracy allows for a fast, accurate solution technique.
