Potential Project Topics

Please feel free to pursue a project not on this list

**Quantum machine learning:** This is somewhat of a controversial topic. There is extreme interest in using quantum computers for machine learning applications, especially from industry. Very recently, some preprints appeared showing that the performance of some proposed quantum algorithms for machine learning is essentially matched by classical algorithms.

Scott Aaronson, “Read the fine print,”

András Gilyén, Seth Lloyd, Ewin Tang, “Quantum-inspired low-rank stochastic regression with logarithmic dependence on the dimension,”
https://arxiv.org/abs/1811.04909

**Quantum walks:** These can be used as quantum analogues of random walks, and have been shown to be useful for algorithmic purposes.

Two survey papers:

J. Kempe, “Quantum random walks – an introductory overview”.

A. Ambainis, “Quantum walks and their algorithmic applications”.

Also, a paper by:

Here are a few more papers in this area. Part of the second reference and the third reference concern a *continuous-time* quantum walk.

C. Moore and A. Russell, “Quantum Walks on the Hypercube”.
A. M. Childs, “Universal computation by quantum walk”.

**Quantum algorithms for solvable groups:** Interesting algorithm for computing the size of solvable groups, and testing membership in such a group.

J. Watrous, “Quantum algorithms for solvable groups”.

**Developments in quantum algorithms for evaluating AND-OR trees:** These can be viewed as trees—such as balanced binary trees—whose gates at each level alternate between AND and OR gates, and whose leaves are labelled $x_1, \ldots, x_n$. The goal is to evaluate the root of the tree with as few queries to the input values as possible. Classically, the cost has been long known to be $O(n^{0.753})$, by an “alpha-beta pruning” technique. It has recently been shown that quantum algorithms can do better than this: $O(n^{0.5})$, for balanced binary trees (and this performance if also known to be optimal). This quantum algorithm has implications for game trees (for example, for more efficient algorithms for Chess and Go).

The development can be traced by the sequence of papers below. The first one is written in a physicist’s language, and the subsequent ones are from a more “computer science” perspective. Nevertheless, this may be a challenging topic to digest in the context of a course project—the recommended approach is to focus technically on one aspect of the subject, while giving a non-technical broad overview to put things in context.

E. Farhi, J. Goldstone, S. Gutmann, “A Quantum Algorithm for the Hamiltonian NAND Tree”.

A. Childs, B. Reichardt, R. Spalek, S. Zhang, “Every NAND formula of size $N$ can be evaluated in time $N^{1/2+o(1)}$ on a quantum computer”.

A. Ambainis, “A nearly optimal discrete query quantum algorithm for evaluating NAND formulas”.

http://arxiv.org/abs/0710.2630

**The theory of fault-tolerant computing:** These (lengthy) papers show that arbitrarily large quantum computers can be built from finite components whose accuracy and
resilience to noise is bounded below some fixed constant. An overview and detailed explanation of some key component of one of these papers would be suitable for a course project.

**Quantum “proof systems”:** A number of results have emerged showing that the expressive power of proof systems increases when quantum information is available.

There are other related topics in various section of the following recent survey monograph

**Continuous-time quantum algorithms:** This is a variant of the query (black-box) model where queries can occur continuously in time.

**Quantum self-testing:** This is about verifying quantum devices that may be provided by adversarial parties.

Classical simulations of stabilizer circuits: This is about an interesting restricted class of quantum circuits that is useful for quantum error-correction, but nevertheless can be efficiently simulated classically.

**The hidden subgroup problem, as well as the hidden shift problem:** Simon’s Algorithm, as well as Shor’s Algorithms for factoring and discrete log can be seen as solving a more abstract problem: the hidden subgroup problem. See also survey (1) for a broad overview.

This paper shows that the general case can be solved very efficiently in terms of black-box queries, but it uses exponentially many auxiliary operations:

This paper considers the hidden subgroup problem for a particular non-abelian group:

Other papers related to the hidden subgroup problem:

Quantum Fourier transforms on general nonabelian groups: A general framework for doing quantum Fourier transforms on certain kinds of nonabelian groups (including the symmetric group)

Quantum Shannon theory: A generalization of classical Shannon theory, concerned with the capacities of noisy channels (quantum and classical). See also surveys (2) and (3) at the end of this document for a broad overview. The fourth reference makes an interesting connection with the so-called “black hole information” paradox.

Quantum algorithms for miscellaneous “traditional” problems: Employs quantum algorithms to obtain speed-ups for various traditional problems in computer science.

**Oracle interrogation:** Addresses the problem of completely determining a function \( f : \{0,1\}^n \rightarrow \{0,1\} \).

**Linear optics:** Proposes problems that are “hard” in a complexity theoretic sense but nevertheless solvable by easily implementable quantum computers. (Warning: the definitions of the problems and their hardness are somewhat subtle.)

**Approximating any unitary gate from a simple set of generating operations:**

**Quantum computation using only measurement gates:**

**Using the mathematics of quantum information to prove theorems:** There are a few mathematical theorems whose statements seem to have nothing to do with quantum information, but which have been reduced to questions about quantum information and then proved by techniques of quantum information. These are applications of quantum computing that stand whether or not one ever builds a quantum computer! (Note: this is quite different from the topic “Quantum ‘proof systems’,” which is also interesting but for different reasons.)

A good survey:

A recent breakthrough, where quantum computing ideas were used to resolve a 20-year-old problem, by proving that linear programs (used in a certain way) cannot be used to solve NP-complete problems:

A nice quantum proof of a classical result in computational complexity about the hardness of computing the permanent:

S. Aaronson, “A Linear-Optical Proof that the Permanent is #P-Hard” http://arxiv.org/abs/1109.1674

**Complexity of finding the minimum eigenvalue of certain Hamiltonians:** Related to the “minimum energy levels” of a certain quantum mechanical systems

**Quantum money:** The idea is for people to circulate quantum states around that have properties that cash has (or should have): it cannot be counterfeited, it’s validity can be checked without having to interact with bank (unlike debit cards), it is anonymous (it cannot be traced back to a spender. With classical information, this is information theoretically impossible, even under cryptographic assumptions about (say) trapdoor or one-way functions. With quantum information and computational assumptions, it is conceivable that this can be done.

Using “nonlocal” behaviour to accomplish various things securely: What can you do securely even if you are using devices supplied by your adversary? Although this may look like a hopeless situation, one can actually use properties of quantum information (in nonlocal settings) to “guarantee” certain things, such as: bit strings actually being certifiable random, cryptographic keys being secure, and more.

Quantum Algorithms for Quantum Field Theories: Using a quantum computer to simulate problems in quantum field theory (where quantum mechanical as well relativistic effects occur). It’s probably good to be already familiar with quantum field theory to tackle this one:

Blind quantum computing: Suppose that you want to compute something on someone else’s quantum computer without revealing any information about what you are computing. This paper addresses this issue:

**Merkle puzzles:** A nice toy problem related to cryptography in a quantum world:

**Surveys:**

These are included for you to peruse for a broad perspective about an “area of research”. You might select a topic based on a specific part of one of these surveys (the entire survey would be long). In some cases, this list (above) or the originally posted list already has an item pertaining to a section of the survey.

**Is boson Sampling computationally hard for classical computers but accomplished by quantum computers?**:

**An interesting connection between state transformation problems and the exponent for matrix multiplication:**

**Quantum information applied to the black hole information loss paradox:**

New developments in query complexity separations:

We have seen the exponential quantum improvement in query-complexity over classical methods for Simon’s problem. Note that Simon’s problem is based on a function with a promise (that most functions from \( \{0,1\}^n \) to \( \{0,1\} \) do not satisfy). On the other hand, Grover’s algorithm, that will be covered later in class, solves a problem that makes sense for any function from \( \{0,1\}^n \) to \( \{0,1\} \). (And the aforementioned AND-OR tree algorithms also address a problem without a promise.) For problems without a promise, until recently, the best quantum improvement has been quadratic (where the quantum algorithm makes a number of queries that is the square root of the number that the best classical algorithm does), and this had been conjectured to be the best possible. Recently, this square root barrier was broken, and the two relevant papers are:

(1) A. Ambainis, K. Balodis, A. Belovs, T. Lee, M. Santha, J. Smotrovs, “Separations in Query Complexity Based on Pointer Functions”

(2) S. Aaronson, S. Ben-David, R. Kothari, “Separations in query complexity using cheat sheets”
https://arxiv.org/abs/1511.01937

They are technical (especially the second one), so please look one of the papers over before selecting it.

Port-based teleportation Suppose you want to do quantum teleportation without having to do a correction operation at the end, at the cost of using more entanglement and settling for imperfect state transfer. This might be a good project if you are already comfortable with the required representation theory.
