NEST ALGEBRAS

Kenneth R. Davidson
# Table of Contents

0. Background
   0.1. Banach Algebras; 0.2. C*-Algebras;
   0.3. Von Neumann Algebras;
   0.4. Compact Operators; 0.5. Bounded Operators.  

I. Compact Operators

1. Ideals of Compact Operators
   Singular values, $C_p$ classes, trace, duality.  

2. Triangular Algebras
   Nests, nest algebras, reflexivity, order type of a nest, the
   diagonal, intervals and homomorphisms.  

3. Triangular Forms for Compact Operators
   Invariant subspaces for compact operators,
   Ringrose’s Theorem, finite rank operators, Erdos Density Theorem,
   Lidskii’s Theorem on the trace.  

4. Triangular Truncation
   Unboundedness of truncation, an integral formula,
   truncation in $C_2$, the Macaev ideal, truncation
   in $C_1$ and $C_\omega$ and its converse.  

5. The Volterra Operator
   Characterization up to unitary equivalence,
   invariant subspaces, singular values, the commutant,
   generators for $\mathcal{T}(LatV)$.  

II Structure of Nest Algebras

6. The Radical
   $Hom(N,2)$, test intervals, characterization
   of the radical, representations of $\mathcal{T}(N)/rad(N)$,
   centre of $\mathcal{T}(N)/rad(N)$.  

7. **Unitary Invariants for Nests**

8. **Expectations**
Basic properties, existence of expectations, uniqueness ?, invariant means, diagonal truncation and triangular truncation revisited, the $R^\infty(M)$ ideal.

9. **Distance Formulae**
Arveson's formula for the distance to a nest algebra, estimates for the distance to AF von Neumann algebras, the abelian case, Stampfli’s formula for distance to the scalars.

10. **Derivations of $C^*$-Algebras**
Bimodules, automatic continuity of derivations of $C^*$ algebras, the bidual of a $C^*$ algebra, weak$^*$ continuity of derivations, derivations of AF von Neumann algebras are inner, the Johnson-Parrott Theorem.

11. **$M$-Ideals**
$M$-ideals, best approximation, ideals of $C^*$ algebras, hereditary properties, approximate identities, distance formulae.

12. **Quasitriangular Algebras**
The algebra $Q(T(M))$, $Q(T(N))$, the distance to $Q(T(N))$; a characterization of $Q(T(M)) = Q(T(M))$, similarly and approximate unitary equivalence of nests, an example.

13. **Similarity and Approximate Unitary Equivalence**
Andersen's Theorem - approximate unitary equivalence of all continuous nests; similarity of continuous nests, absolute continuity and partitions, Similarity Theorem, the $R^\infty(M)$ ideal.
III Additional Topics

14. Factorization
Factorization of positive operators as $P = T T$ for $T$ in $\mathcal{T}(\mathcal{A})$, factorization of invertible operators in $\mathcal{T}(\mathcal{A})$, the role of the Macaev ideal, outer operators, factorization in well ordered nests. 177

15. Reflexivity, Ideals, and Bimodules
1. Utility grade tensor products; 2. Reflexivity, bimodules for a masa in $\mathcal{B}(\mathcal{A})$, nest algebras;
3. Weak* closed ideals of $\mathcal{T}(\mathcal{A})$, generators;
4. Interpolation: when $A_1, ..., A_n$ generate $\mathcal{T}(\mathcal{A})$ as a left ideal; 5. Invariant operator ranges, Foias’s Theorem, invariant ranges for CSL algebras. 193

16. Duality
The predual of $\mathcal{T}(\mathcal{A})$, extreme points, new proofs of Erdos Density Theorem, Arveson’s Distance Formula, and Lidskii’s Theorem, decomposition of trace class operators in $\mathcal{T}(\mathcal{A})$ as sums of rank one operators. 217

17. Isomorphisms
Isomorphisms of masas, automatic continuity of isomorphisms of nest algebras, isomorphisms of the finite rank operators, automorphisms of nest algebras are spatial, the outer automorphism group, the quasitriangular algebra and its outer automorphism group. 233

18. Perturbations of Operator Algebras
Hausdorff distance for subspaces, perturbation of CSL algebras, nest algebras, perturbation of abelian von Neumann algebras and their commutants. 255

19. Derivations and Cohomology
Automatic continuity, derivations of $\mathcal{T}(\mathcal{A})$ are inner, derivations of $\mathcal{Q}(\mathcal{T}(\mathcal{A}))$ are inner, essential commutant of $\mathcal{T}(\mathcal{A})$, compact derivations, pointwise limits of derivations. Appendix: $K_0$ of a nest algebra. Notes; cohomology of nest algebras. 267
20. **Representations and Dilations Theory**

21. **Operators in Nest Algebras**
1. Unicellular operators, construction of examples. 2. Unitary orbits of nest algebras, Herero’s Theorem.

IV **CSL Algebras**

22. **Commutative Subspace Lattices**
A representation theorem, pseudo integral operators, reflexivity, $A_{\text{min}}(L)$, synthetic lattices, generators. Appendix: product formula for pseudo integral operators.

23. **Complete Distributivity and Compact Operators**
Completely distributive lattices, rank one operators in CSL algebras SOT compactness, finite rank operators, examples of CSL algebras with few compact operators.

24. **Failure of the Distance Formula**
Examples of CSL algebras which are not hyperreflexive, the dual product construction.

25. **Open Problems**

**BIBLIOGRAPHY**

**INDEX**
Preface

The study of triangular forms for operators began in the late 50's and early 60's with the work on triangular integrals of the Russian school (Gohberg, Krein, et al) and the work of Ringrose. It was Ringrose who initiated the study of the algebra of all operators with a given triangular form. He coined the term "nest algebra" since the more natural term "triangular algebra" had recently been taken by Kadison and Singer for a related class of algebras. While one cannot claim that the study of these algebras is near completion, one can say that the subject has reached a certain maturity. This is due in part to a complete solution of the similarity problem for nests proposed by Ringrose in his early work. This solution, due to Andersen, Larson, and the author, is the main focus of part II of this monograph.

The intent of these notes is to present this material for the benefit of graduate students with a background in functional analysis. It is hoped that it will also be of use to other experts, but of course one could be more terse for such an audience. Only a basic knowledge of $C^*$-algebras and von Neumann algebras is assumed. Indeed, many results for $C^*$-algebras and type I von Neumann algebras are developed carefully here. This subject of non self adjoint operator algebras is attractive, in part, due to the nice blend of single operator theory and self adjoint algebra theory.

There is a larger related class of reflexive algebras (CSL algebras) introduced by Arveson which receives the attention of many researchers interested in nest algebras. The theory of these algebras is much less well understood. So we have chosen only to introduce a small portion of this material at the end of the book. However, wherever possible, the proofs provided in the nest case are chosen so that they extend to other CSL lattices.

The first part of this monograph concentrates on the structure of compact operators. This goes substantially beyond what is normally done in an introductory course in operator theory. But it is elegant and substantial mathematics that should be familiar to more operator theorists. Some of this material is available in the books of Ringrose [5] and Gohberg and Krein [1, 2]. But our viewpoint is more up to date, and many of the proofs are different.

The second part deals with basic structural properties of nest algebras - the radical, unitary invariants, and similarity invariants. The third part deals with further structural properties of nest algebras. It is not always necessary to read what has come before, so a flow chart has been
provided for the reader's convenience. The last short part is an introduction to CSL algebras.

These notes in a preliminary form were used for a graduate course taught at the University of Waterloo in winter 1987. There is too much material here for a one semester course. Indeed, it was necessary to pick and choose a narrow path in order to get to the Similarity Theorem in one term. I would like to thank D. Casperson, D. Dicks, L. Marcoux, and F. Zorzitto for numerous helpful criticisms. Also, I would like to thank Mrs. B. Law for her technical expertise in typing this manuscript.

An asterisk * on an exercise means that I do not know the answer. It does not necessarily mean that it is an important problem.

Kenneth R. Davidson
Waterloo, 1987
0. Background

In this chapter, we review briefly some of the facts about Hilbert space operators and $C^*$-algebras which will be needed to read this book. Most of the material can be found in introductory textbooks such as Conway [1], Douglas [2], or Kadison-Ringrose [3].

0.1 Banach Algebras

A Banach algebra is a Banach space $\mathcal{A}$ over $\mathbb{C}$ which is also an (associative) algebra over $\mathbb{C}$ such that $\|AB\| \leq \|A\| \|B\|$ for all $A, B$ in $\mathcal{A}$. When $\mathcal{A}$ has a unit $I$, the spectrum $\sigma(A)$ (or $\sigma_{\mathcal{A}}(A)$ if $\mathcal{A}$ needs to be clarified) is the set $\{\lambda \in \mathbb{C} : A - \lambda I$ is not invertible in $\mathcal{A}\}$. This is a non-empty compact set. The spectral radius

$$spr(A) = \sup\{|\lambda| : \lambda \in \sigma(A)\} = \lim_{n \to \infty} \|A^n\|^{1/n}.$$ 

Let $f$ be holomorphic in a neighbourhood $G$ of $\sigma(A)$, and let $C$ be a finite union of Jordan curves such that $\text{ind}_C(\lambda) = 1$ for every $\lambda$ in $\sigma(A)$. Define

$$f(A) = \frac{1}{2\pi i} \int_C f(z)(zI-A)^{-1}dz.$$ 

Let $\text{Hol}(\sigma(A))$ denote the set of functions holomorphic in some neighbourhood of $\sigma(A)$.

Riesz Functional Calculus. Let $A$ be an element of a Banach algebra $\mathcal{A}$ with identity. Then for every $f$ in $\text{Hol}(\sigma(A))$, $f(A)$ is well defined independent of the curve $C$. The map taking $f$ to $f(A)$ is an algebra homomorphism such that each polynomial $p(z) = \sum_{k=0}^{n} c_k z^k$ is taken to $c_0 I + \sum_{k=1}^{n} c_k A^k$.

Let $\mathcal{A}$ be an abelian Banach algebra with identity. A multiplicative linear functional is an algebra homomorphism $\phi$ into $\mathbb{C}$. Such functionals are always continuous with $\|\phi\| = 1$. They are in a one to one correspondence with the maximal ideals of $\mathcal{A}$. The set $M_{\mathcal{A}}$ of maximal ideals is
given the weak* topology induced as a subset of the dual space $\mathcal{A}'$. It is easy to verify that $M_\mathcal{A}$ is closed, and thus is compact by the Banach-Alaoglu Theorem. There is a natural homomorphism of $\mathcal{A}$ into $C(M_\mathcal{A})$, called the Gelfand transform, is given by $\hat{\phi} = \phi(A)$.

**Gelfand's Theorem.** The Gelfand transform $A \rightarrow \hat{A}$ of $\mathcal{A}$ into $C(M_\mathcal{A})$ is a continuous algebra homomorphism such that $\|\hat{A}\| \leq \|A\|$. Furthermore,

$$\sigma(A) = \sigma(\hat{A}) = \text{Ran}(\hat{A}) = \{\phi(A): \phi \in M_\mathcal{A}\}.$$ 

The kernel of this map is

$$\text{rad}(\mathcal{A}) = \bigcap \{\text{ker } \phi: \phi \in M_\mathcal{A}\} = \{A \in \mathcal{A}: \sigma(A) = \{0\}\}.$$

An immediate corollary is the:

**Spectral Mapping Theorem.** For $f$ in the $\text{Hol}(\sigma(A))$,

$$\sigma(f(A)) = f(\sigma(A)).$$

### 0.2 $C^*$-Algebras

A $C^*$-algebra is a Banach algebra with a conjugation operation $\ast$ such that $(A^*)^* = A$, $(AB)^* = B^*A^*$, $(\alpha A + \beta B)^* = \bar{\alpha} A^* + \bar{\beta} B^*$, and $\|A^*A\| = \|A\|^2$. (That is, $A \rightarrow A^*$ is an involution and a conjugate linear anti-isomorphism satisfying the special norm condition $\|A^*A\| = \|A\|^2$.)

The main (and in a certain sense only) examples are self-adjoint subalgebras of $B(\mathcal{H})$.

**Gelfand-Naimark Theorem.** If $\mathcal{A}$ is an abelian $C^*$-algebra with identity, then the Gelfand transform is an isometric $\ast$-isomorphism of $\mathcal{A}$ onto $C(M_\mathcal{A})$.

An element $N$ of a $C^*$-algebra $\mathcal{A}$ is normal if $N^*N = NN^*$. This occurs precisely when the sub $C^*$-algebra $C^*(N)$ generated by $N$ is abelian. Thus one obtains the immediate corollary:

**$C^*$-Functional Calculus.** If $N$ is a normal element of a $C^*$-algebra, then $C^*(N)$ is isometrically $\ast$-isomorphic to $C(\sigma(N))$. The inverse map yields a functional calculus extending the Riesz Functional Calculus such that $f(N) = f(N)^*$, and $\sigma(f(N)) = f(\sigma(N))$ for all $f$ in $C(\sigma(N))$. 
Every (two-sided, closed) ideal \( I \) of a \( C^* \)-algebra \( \mathcal{A} \) is self-adjoint, and \( \mathcal{A} / I \) is a \( C^* \)-algebra. Furthermore,

**Proposition.** Let \( \pi \) be a \( * \)-homomorphism of a \( C^* \)-algebra \( \mathcal{A} \) into a \( C^* \)-algebra \( B \). Then \( \| \pi \| = 1 \), \( \text{Ran}(\pi) \) is closed and is isometrically \( * \)-isomorphic to \( \mathcal{A} / \ker \pi \).

An element \( P \) of a \( C^* \)-algebra is **positive** if it is self-adjoint with positive spectrum. By the functional calculus, \( P = A^* A \) where \( A = P^{1/2} \). Conversely, every operator of the form \( A^* A \) is positive (even if \( A \) is not normal). A **positive linear functional** is a linear map of \( \mathcal{A} \) into \( \mathbb{C} \) such that \( f(A) \geq 0 \) whenever \( A \geq 0 \). The two variable function \( [A, B] = f(B^* A) \) is a sesquilinear form on \( \mathcal{A} \times \mathcal{A} \). The Cauchy-Schwartz inequality becomes

\[
|f(B^* A)|^2 \leq f(A^* A) f(B^* B).
\]

It follows easily from positivity that if \( 0 \leq A \leq I \), then \( 0 \leq f(A) \leq f(I) \). Hence if \( \| A \| \leq 1 \),

\[
|f(A)|^2 = |f(A^* A)|^2 \leq f(A^* A) f(I) \leq f(I)^2.
\]

So \( \| f \| = \| f(I) \| \) and \( f \) is continuous. A **state** is a positive linear functional with \( f(I) = 1 \).

A representation of a \( C^* \)-algebra \( \mathcal{A} \) is a \( * \)-homomorphism \( \pi \) of \( \mathcal{A} \) into \( \mathcal{B}(\mathcal{H}) \). This representation is **cyclic** if there is a cyclic vector \( x \) with \( \{ \pi(A)x : A \in \mathcal{A} \} \) dense in \( \mathcal{H} \). A representation is **non-degenerate** if \( \pi(\mathcal{A}) \) has no kernel. It is easy to check that every non-degenerate representation is unitarily equivalent to a direct sum of cyclic ones.

**Gelfand-Naimark-Segal Theorem.** Let \( \mathcal{A} \) be a \( C^* \)-algebra with identity. Given a state on \( \mathcal{A} \), there is a cyclic representation \( \pi_f \) on \( \mathcal{H}_f \) with cyclic vector \( \xi_f \) such that \( f(A) = (\pi_f(A)\xi_f, \xi_f) \). Conversely, given a cyclic representation \( \pi \) with unit cyclic vector \( \xi \), let \( f(A) = (\pi(A)\xi, \xi) \). Then there is a unitary \( U \) of \( \mathcal{H}_f \) onto \( \mathcal{H} \) such that \( U\xi_f = \xi \), and \( \pi(A) = U\pi_f(A)U^* \) for every \( A \) in \( \mathcal{A} \).

One can show that every \( C^* \)-algebra has enough states \( S(\mathcal{A}) \) so that \( \| A \| = \sup \{ \| f(A) \| : f \in S(\mathcal{A}) \} \). Thus by taking a direct sum of the representations from the GNS construction, one obtains:

**Corollary.** Every \( C^* \)-algebra is isometrically \( * \)-isomorphic to a subalgebra of \( \mathcal{B}(\mathcal{H}) \).
0.3 Von Neumann Algebras

The weak operator topology on $B(\mathcal{H})$ is the weakest topology such that the functionals $\phi(T) = \langle Tx, y \rangle$ are continuous for every $x$ and $y$ in $\mathcal{H}$. The strong operator topology is the weakest topology such that the map $T \mapsto \|Tx\|$ is continuous for all $x$ in $\mathcal{H}$. It will be seen (Theorem 1.15) that $B(\mathcal{H})$ is the dual space of the trace class operators. So it has a weak $*$-topology (sometimes called the ultra-weak topology). This is the weakest topology such that the trace $\text{tr}(CT)$ is a continuous function of $T$ for every trace class operator $C$. The weak operator continuous functionals are precisely those where $C$ is finite rank. There are several other related topologies, but these will generally suffice for our purposes.

A von Neumann algebra is a $C^*$-subalgebra of $B(\mathcal{H})$ containing the identity which is closed in the weak operator topology. If $A$ is a subset of $B(\mathcal{H})$, the commutant $A' = \{T \in B(\mathcal{H}): AT = TA \text{ for all } A \text{ in } A\}$. The von Neumann algebra generated by a single operator $T$ is denoted by $W^*(T)$. There are two basic density theorems that we will require.

**The von Neumann Double Commutant Theorem.** Let $A$ be a $C^*$-subalgebra of $B(\mathcal{H})$. Then the closure of $A$ in any of the weak operator, strong operator, and weak* topologies is the double commutant $A''$.

**Kaplansky's Density Theorem.** Let $A$ be a $C^*$-subalgebra acting on a separable Hilbert space $\mathcal{H}$. Then every operator in the unit ball of $A''$ is the strong operator limit of a sequence of operators in the unit ball of $A$. The self-adjoint part of the ball of $A$ is likewise strongly dense in the self-adjoint part of the ball of $A''$.

By the Banach-Alaoglu Theorem, the unit ball of $B(\mathcal{H})$ is compact in the weak* topology. Thus it is also compact in the weak operator topology since it is a weaker topology. It is not, however, compact in the strong operator topology. Multiplication is separately continuous but not jointly continuous in any of these topologies. However, in the strong operator topology, multiplication is jointly continuous on the unit ball. The adjoint operation is continuous in the weak operator and weak* topologies, but not in the strong operator topology. The strong* topology is the weakest topology containing the strong topology in which adjoint is continuous.
0.4 Compact Operators

An operator $K$ is compact if the image of the unit ball of $\mathcal{H}$ under $K$ has compact closure. (In fact, the image of the unit ball under $K$ is closed). Let $\{e_n, n \geq 1\}$ be an orthonormal basis, and let $P_n$ be the orthogonal projection onto $\text{span}\{e_k, 1 \leq k \leq n\}$. It is not hard to show that a compact operator $K$ is the norm limit of the finite rank operators $P_nK$. The following results are standard.

**Theorem.** For an operator $K$ on Hilbert space, the following are equivalent:

(i) $K$ is compact,  
(ii) $K^*$ is compact,  
(iii) $K$ is the norm limit of finite rank operators.

**Theorem.** Let $K$ be a compact operator. Then $\sigma(K)$ consists of $\{0\}$ together with a finite or countable set $\{\lambda_k\}$ of eigenvalues with $\{0\}$ as its only limit point. The Riesz projections $E_{K_{\lambda_k}}$ are finite rank, and have range equal to $\ker(K - \lambda_k I)^{k_n}$ for $k_n$ sufficiently large.

When $K$ is normal and compact, one obtains:

**Spectral Theorem (Compact Case).** Let $K$ be a compact, normal operator on $\mathcal{H}$. Then there is an orthonormal basis $\{e_n\}$ of eigenvectors with eigenvalues $\{\lambda_n\}$ such that $\lim_{n \to \infty} \lambda_n = 0$. So $K(\sum_{n=1}^{\infty} a_n e_n) = \sum_{n=1}^{\infty} \lambda_n a_n e_n$.

0.5 Bounded Operators

Let $T$ be a bounded operator on Hilbert space. The absolute value of $T$ is the positive operator $|T| = (T^*T)^{1/2}$. It is easy to check that $\| |T| x \| = \| Tx \|$ for every $x$ in $\mathcal{H}$. So one can define a partial isometry $U$ so that $U |T| x = Tx$ and $U y = 0$ for $y$ in $\ker T$. Then $UU^*$ is the projection onto the closure of the range, $\text{Ran}(T)$ and $U^*U$ is the projection onto $(\ker T)\perp$. One obtains the polar decomposition $T = U |T|$.
For normal operators, one has the Spectral Theorem. More detail will be obtained in Chapter 6.

**Spectral Theorem.** Let $N$ be a normal operator on Hilbert space. There is a countably additive, regular Borel measure $E_n$ on $\mathcal{C}$ with values in the projections onto subspaces of $\mathcal{H}$ such that:

(i) $E_N(\sigma(N)) = I$,

(ii) $N = \int zdE_N(z)$,

(iii) $E_N(X)$ commutes with every operator commuting with $N$, for every Borel set $X$,

(iv) if $f$ is bounded Borel function, let $f(N) = \int f(z)dE_N(z)$. This is a homomorphism from the bounded Borel functions on $\mathcal{C}$ onto $W^*(\mathcal{N})$ extending the $C^*$ functional calculus of $N$.

Another special property of normal operators is:

**Fuglede's Theorem.** Let $N$ be a normal operator, and let $A$ be a bounded operator such that $NA = AN$. Then $N^*A = AN^*$.

**Corollary.** $\{N\}' = \{A: AN = NA\}$ is a von Neumann algebra when $N$ is normal.

The quotient $C^*$-algebra $A = B(\mathcal{H})/K$ is called the Calkin algebra. The image of an operator $T$ in $A$ will be denoted by $\bar{T}$. An operator $T$ is called Fredholm if $T$ has closed range, and both $\ker T$ and $\ker T^* = \text{Ran}(T)^\perp$ are finite dimensional. The Fredholm index is defined as

$$\text{ind} T = \text{dim} \ker T - \text{dim} \ker T^* .$$

**Atkinson's Theorem.** An operator $T$ in $B(\mathcal{H})$ is Fredholm if and only if $\bar{T}$ is invertible in the Calkin algebra.

Thus the set of Fredholm operators $\mathcal{F}(\mathcal{H})$ is open in $B(\mathcal{H})$. The Fredholm index is continuous, and hence locally constant, and is invariant under compact perturbations. Furthermore
Theorem. The Fredholm index is a continuous algebra homomorphism of \( F(\mathcal{H}) \) onto \( \mathbb{Z} \). The kernel is the connected component of the identity in \( F(\mathcal{H}) \).

The essential spectrum of an operator \( T \), denoted \( \sigma_e(T) \), is \( \sigma(\tilde{T}) \) in the Calkin algebra. The complement \( \sigma(T) \setminus \sigma_e(T) \) consists of countably many bounded components of the complement of \( \sigma(T) \) on which \( T - \lambda I \) is Fredholm of some fixed index, together with countably many isolated points of finite multiplicity clustering at \( \sigma_e(T) \).
I. COMPACT ALGEBRAS

1. Ideals of Compact Operators
2. Triangular Algebras
3. Triangular Forms for Compact Operators
4. Triangular Truncation
5. The Volterra Operator
1. Ideals of Compact Operators

In this chapter, we investigate various ideals of $\mathcal{B}(\mathcal{H})$. The first result justifies the title of this chapter.

1.1 Proposition. The only proper closed ideal in $\mathcal{B}(\mathcal{H})$ for a separable Hilbert space $\mathcal{H}$ is the set $K$ of compact operators.

Proof. Let $T$ be a non-compact operator. By the polar decomposition, $T = U \sqrt{|T|}$ and $|T|$ is not compact. So there is an infinite dimensional spectral projection $E$ of $|T|$ on which $T$ is bounded below. The operator $V = E \sqrt{|T|} + E^\perp$ is invertible, and $E = V^{-1}U^*TE$. Thus $E$ belongs to the two sided ideal generated by $T$. From this, it easily follows that this ideal is all of $\mathcal{B}(\mathcal{H})$. On the other hand, if $K$ is a non-zero compact operator, a similar argument shows that the ideal generated by $K$ contains a rank one projection. Hence it contains all finite rank operators, which are dense in $K$. 

1.2. Let $K$ be a compact operator. The positive operator $|K| = (K^*K)^{1/2}$ has eigenvalues $\lambda_1 \geq \lambda_2 \geq ...$ with $\lim_{n \to \infty} \lambda_n = 0$. The $s$-numbers or singular values of $K$ are the numbers $s_n = s_n(K)$. Let $\{\epsilon_n, n \geq 1\}$ be an orthonormal set of eigenvectors of $|K|$ for the eigenvalues $s_n(K)$. Let $f_n = U\epsilon_n$. Then

$$K = \sum_{n=1}^{\infty} s_n f_n \otimes e_n^*$$

and this sum is norm convergent. Here $x \otimes y^*$ denotes the rank one operator

$$x \otimes y^*(x) = \langle z, y \rangle x$$

The identity $A(x \otimes y^*)B = Ax \otimes (B^*y)^*$ is readily verified.

For $1 \leq p \leq \infty$ let $\mathcal{C}_p$ denote the Schatten $p$-class of all compact operators $K$ such that $\{s_n(K)\}$ belongs to $\ell^p$. Define a norm on $\mathcal{C}_p$ by

$$\|K\|_p = \left( \sum_{n \geq 1} s_n(K)^p \right)^{1/p}$$

Of particular interest are the trace class operators $\mathcal{C}_1$, and the Hilbert-Schmidt operators $\mathcal{C}_2$. 

11
1.3 Theorem. Let $K = \sum_{n=1}^{\infty} f_n \otimes e_n^*$ be a trace class operator. Then for every orthonormal bases $\{\phi_k\}$ and $\{\psi_k\}$, one has

$$\sum_{k=1}^{\infty} |(K\phi_k,\psi_k)| \leq \|K\|_1$$

and

$$\sum_{k=1}^{\infty} (K\phi_k,\phi_k) = \sum_{k=1}^{\infty} s_n(f_n,e_n) .$$

Proof. Using the Cauchy-Schwartz inequality and the Parseval identity,

$$\sum_{k=1}^{\infty} |(K\phi_k,\psi_k)| \leq \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} |(e_n,\phi_k)| |(f_n,\psi_k)|$$

$$= \sum_{n=1}^{\infty} s_n \sum_{k=1}^{\infty} |(e_n,\phi_k)| |(f_n,\psi_k)|$$

$$\leq \sum_{n=1}^{\infty} s_n \left( \sum_{k=1}^{\infty} |(e_n,\phi_k)|^2 \right)^{\frac{1}{2}} \left( \sum_{k=1}^{\infty} |(f_n,\psi_k)|^2 \right)^{\frac{1}{2}}$$

$$= \sum_{n=1}^{\infty} s_n = \|K\|_1 .$$

Now taking $\psi_k = \phi_k$, one obtains an absolutely convergent series. Thus

$$\sum_{k=1}^{\infty} (K\phi_k,\phi_k) = \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} |(e_n,\phi_k)|^2 |(f_n,\psi_k)|$$

$$= \sum_{n=1}^{\infty} s_n \sum_{k=1}^{\infty} |(f_n,\phi_k)(e_n,\psi_k)| = \sum_{n=1}^{\infty} s_n(f_n,e_n) .$$

Consequently, one may define a well defined continuous linear functional known as the trace on $C_1$ by

$$tr(K) = \sum_{n=1}^{\infty} (K\phi_n,\phi_n) .$$

This is independent of the choice of orthonormal basis.

Now we develop some basic inequalities about $s$-numbers.

1.4 Lemma. Let $K$ be a compact operator. Then

$$s_n(K) = \inf \{ \|K - F\| : \text{rank } F \leq n-1 \} .$$
Proof. Let \( K = \sum_{n=1}^{\infty} s_n f_n \otimes e^*_n \). Then \( F_n = \sum_{k=1}^{n-1} s_k f_k \otimes e^*_k \) has rank \( n-1 \), and \( K-F_n = \sum_{k=n}^{\infty} s_k f_k \otimes e^*_k \). So

\[
s_n(K) = \|K-F_n\| \geq \inf\{\|K-F\| : \text{rank } F \leq n-1\}.
\]

On the other hand, if \( \text{rank } F \leq n-1 \), there is a unit vector \( x \) in the intersection \( \ker F \cap \text{span} \{e_k, 1 \leq k \leq n\} \). So

\[
\|K-F\| \geq \|(K-F)x\| = \|Kx\| = \left\| \sum_{k=1}^{n} s_k (x,e_k) f_k \right\| \geq s_n \sum_{k=1}^{n} \|(x,e_k)^2 f_k^2 = s_n.
\]

1.5 Corollary. Let \( K \) be compact, and let \( T \) be a bounded operator. Then

\[
s_n(TK) \leq \|T\|s_n(K) \text{ and } s_n(KT) \leq \|T\|s_n(K).
\]

Proof. Let \( F_n \) be the operators defined above. Then

\[
s_n(TK) \leq \|TK - TF_n\| \leq \|T\| \|K-F_n\| = \|T\|s_n(K).
\]

\[
s_n(KT) \leq \|KT - F_nT\| \leq \|K-F_n\| \|T\| = \|T\|s_n(K).
\]

1.6 Corollary. \( C_p \) is a self-adjoint ideal in \( B(\mathcal{H}) \), and \( \|TKS\|_p \leq \|T\| \|K\|_p \|S\| \) for all \( K \) in \( C_p \) and \( T, S \) in \( B(\mathcal{H}) \).

Proof. Since \( s_n(TKS) \leq \|S\| \|T\|s_n(K) \), this belongs to \( \ell^p \) and satisfies the desired inequality. That \( C_p \) is a linear space follows for if \( K_1, K_2 \) belongs to \( C_p \) and \( F_n^{(i)} \) are the finite rank operators of the previous lemma, then

\[
s_{2n}(K_1+K_2) \leq s_{\infty}(K_1+K_2) \leq \|K_1+K_2-F_n^{(i)} - F_n^{(2)}\| \leq s_n(K_1) + s_n(K_2).
\]

So \( \|K_1+K_2\|_p \leq 2^{1/p} (\|K_1\|_p + \|K_2\|_p) \). If \( K = \sum_{n=1}^{\infty} s_n(f_n \otimes e^*_n) \), then \( K^* = \sum_{n=1}^{\infty} s_n(e_n \otimes f^*_n) \). So \( s_n(K^*) = s_n(K) \) for \( n \geq 1 \). So \( \|K^*\|_p = \|K\|_p \), and therefore \( C_p \) is self-adjoint.
To obtain the triangle inequality for the $C_p$ norm, we need some more inequalities.

1.7 Lemma. Let $K$ be a compact operator. If $\{\phi_k, 1 \leq k \leq n\}$ and $\{\psi_k, 1 \leq k \leq n\}$ are orthonormal families, then

$$\sum_{k=1}^{n} |(K\phi_k, \psi_k)| \leq \sum_{k=1}^{n} \sigma_k(K).$$

Proof. Replace $\psi_k$ by a scalar multiple so that $(K\phi_k, \psi_k) \geq 0$ for $1 \leq k \leq n$. Let $U$ be the rank $\text{rank} n$ partial isometry such that $U\psi_k = \phi_k$ for $1 \leq k \leq n$. Then $\sigma_k(KU) \leq \sigma_k(K)$ for $1 \leq k \leq n$, and $\sigma_k(KU) = 0$ for $k > n$ as $\text{rank}(KU) \leq n$. Hence

$$\sum_{k=1}^{n} (K\phi_k, \psi_k) = \sum_{k=1}^{n} (KU\psi_k, \psi_k) = \text{tr}(KU) \leq \|KU\|_1 = \sum_{k=1}^{n} \sigma_k(KU) \leq \sum_{k=1}^{n} \sigma_k(K).$$

1.8 Corollary. Let $K_1$ and $K_2$ be compact operators. Then

$$\sum_{k=1}^{n} \sigma_k(K_1 + K_2) \leq \sum_{k=1}^{n} \sigma_k(K_1) + \sigma_k(K_2).$$

Proof. Write $K_1 + K_2 = \sum_{k=1}^{\infty} \sigma_k f_k \otimes \sigma_k e_k$ where $\sigma_k = \sigma_k(K_1 + K_2)$. Then

$$\sum_{k=1}^{n} \sigma_k(K_1 + K_2) = \sum_{k=1}^{n} (K_1 + K_2) e_k, f_k) \leq \sum_{k=1}^{n} |(K_1 e_k, f_k)| + |(K_2 e_k, f_k)| \leq \sum_{k=1}^{n} \sigma_k(K_1) + \sigma_k(K_2).$$

1.9 Corollary. Let $K_1$ and $K_2$ belong to $C_p$, $1 \leq p \leq \infty$. Then

$$\|K_1 + K_2\|_p \leq \|K_1\|_p + \|K_2\|_p.$$
Proof. The case $p = 1$ is immediate from Corollary 1.8, and $p = \infty$ is the usual operator norm. So suppose $1 < p < \infty$. Let $\lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_{n+1} = 0$ be a decreasing sequence of positive real numbers. By "summation by parts", one obtains

$$\sum_{k=1}^{n} \lambda_k s_k(K_1 + K_2) = \sum_{j=1}^{n} (\lambda_j - \lambda_{j+1}) \sum_{k=1}^{j} s_k(K_1 + K_2)$$

$$\leq \sum_{j=1}^{n} (\lambda_j - \lambda_{j+1}) \sum_{k=1}^{j} s_k(K_1) + s_k(K_2)$$

$$= \sum_{k=1}^{n} \lambda_k (s_k(K_1) + s_k(K_2)) .$$

Let $1 < q < \infty$ be such that $1/p + 1/q = 1$. Let $\lambda_k = s_k(K_1 + K_2)^{p/q} = s_k(K_1 + K_2)^{p-1}$. By Hölder’s inequality,

$$\sum_{k=1}^{n} s_k(K_1 + K_2)^{p} = \sum_{k=1}^{n} \lambda_k s_k(K_1 + K_2)$$

$$\leq \sum_{k=1}^{n} \lambda_k s_k(K_1) + \sum_{k=1}^{n} \lambda_k s_k(K_2)$$

$$\leq (\sum_{k=1}^{n} \lambda_k^{1/q}) (\sum_{k=1}^{n} s_k(K_1)^{p^{1/q}}) + (\sum_{k=1}^{n} \lambda_k^{1/q}) (\sum_{k=1}^{n} s_k(K_2)^{p^{1/q}})$$

$$\leq (\sum_{k=1}^{n} s_k(K_1 + K_2)^{p})^{1/q} (\|K_1\|_p + \|K_2\|_p) .$$

Hence

$$\left( \sum_{k=1}^{n} s_k(K_1 + K_2)^{p} \right)^{1/p} \leq \|K_1\|_p + \|K_2\|_p .$$

Taking a limit as $n$ increases yields $\|K_1 + K_2\|_p \leq \|K_1\|_p + \|K_2\|_p . \quad \blacksquare$

We extract from this proof another technical inequality.

1.10 Lemma. Let $K$ be a compact operator, and let $\lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_{n+1} = 0$ be a decreasing sequence of positive real numbers. Let $\{\phi_k, 1 \leq k \leq n\}$ and $\{\psi_k, 1 \leq k \leq n\}$ be orthonormal sets. Then

$$\sum_{k=1}^{n} \lambda_k \| (K\phi_k, \psi_k) \| \leq \sum_{k=1}^{n} \lambda_k s_k(K) .$$

Proof. This is a simple summation by parts argument together with Lemma 1.7.
\[
\sum_{k=1}^{n} \lambda_k |(K \phi_k, \psi_k)| = \sum_{j=1}^{n} (\lambda_j - \lambda_{j-1}) \sum_{k=1}^{j} |(K \phi_k, \psi_k)| \\
\leq \sum_{j=1}^{n} (\lambda_j - \lambda_{j-1}) \sum_{k=1}^{j} s_k(K) = \sum_{k=1}^{n} \lambda_k s_k(K). \quad \blacksquare
\]

Now we are ready to prove that \( C_p \) is complete. Let \( \mathcal{I} \) denote the set of finite rank operators.

**1.11 Theorem.** \( C_p \) is a Banach space for \( 1 \leq p \leq \infty \), and \( \mathcal{I} \) is dense in \( C_p \).

**Proof.** It must be shown that \( C_p \) is complete. If \( K \) is in \( C_p \), then

\[
\|K\| = s_1(K) \leq (\sum_{k \geq 1} s_k(K)^p)^{1/p} = \|K\|_p.
\]

So if \( K_j \) is a Cauchy sequence in \( C_p \), then it is Cauchy in \( K \). Thus \( K = \lim_{j \to \infty} K_j \) exists in \( K \). A fortiori,

\[
(Kx, y) = \lim_{j \to \infty} (K_jx, y)
\]

for every pair of vectors \( x \) and \( y \) in \( \mathcal{H} \). Let \( s_n = s_n(K) \) and choose orthonormal sets \( \{e_n\} \) and \( \{f_n\} \) so that \( K = \sum_{n=1}^{\infty} s_n(f_n \otimes e_n^*) \). By Lemma 1.10 and Hölder's inequality,

\[
\sum_{k=1}^{n} s_k^p = \sum_{k=1}^{n} \frac{s_k^p}{q} (K e_n, f_n) = \lim_{j \to \infty} \left( \sum_{k=1}^{n} \frac{s_k^p}{q} (K_j e_n, f_n) \right)
\]

\[
\leq \liminf_{j \to \infty} \sum_{k=1}^{n} s_k^{p/q} s_k(K_j)
\]

\[
\leq \liminf_{j \to \infty} \left( \sum_{k=1}^{n} s_k^p \right)^{1/q} \left( \sum_{k=1}^{n} s_k^q \right)^{1/p}
\]

\[
= (\sum_{k=1}^{n} s_k^p)^{1/q} \lim_{j \to \infty} \|K_j\|_p.
\]

Note that \( \|K_j\|_p \) converges since \( \|K_j\|_p - \|K_k\|_p \leq \|K_j - K_k\|_p \) by the triangle inequality, and so \( \|K_j\|_p \) is Cauchy. Thus we obtain

\[
(\sum_{k=1}^{n} s_k^p)^{1/p} \leq \lim_{j \to \infty} \|K_j\|_p.
\]

Taking a limit as \( n \) increases yields \( \|K\|_p \leq \lim_{j \to \infty} \|K_j\|_p \), so \( K \) belongs to \( C_p \). Apply this same inequality to \( K - K_n \) to obtain
\[ \|K - K_n\|_p \leq \lim_{j \to \infty} \|K_j - K_n\|_p. \]

As \(K_j\) is Cauchy, the right hand side tends to zero as \(n\) increases. So \(K_n\) converges to \(K\) in the \(C_p\) norm.

Given \(K\) in \(C_p\) represented as above, the finite rank operators \(F_n = \sum_{k=1}^{n} \delta_k(f_k \otimes \epsilon_k)\) clearly converge to \(K\) in \(C_p\). So \(F\) is dense in \(C_p\). \(\blacksquare\)

1.12 Theorem. Let \(K\) belong to \(C_p\), \(1 \leq p \leq \infty\) and \(1/p + 1/q = 1\). Then for every \(T\) in \(C_q\), \(KT\) belongs to \(C_1\) and \(\phi_K(T) = tr(KT)\) is a linear functional on \(C_q\) with \(\|\phi_K\| = \|K\|_p\).

Proof. Let \(s_n = s_n(K)\) and \(K = \sum_{n=1}^{\infty} s_n(f_n \otimes \epsilon_n^*)\). Let \(t_n = s_n(T)\). Also, \(KT\) can be written as \(KT = \sum_{n=1}^{\infty} s_n(KT) \phi_n \otimes \psi_n^*\). Let \(U_N\) be the rank \(N\) partial isometry such that \(U_N \phi_n = \psi_n\) for \(1 \leq n \leq N\). Then

\[
\sum_{n=1}^{N} s_n(KT) = \sum_{n=1}^{N} (KT \phi_n, U_N \phi_n) = \sum_{n=1}^{N} (T \phi_n, K^* U_N \phi_n)
\]

\[
= \sum_{n=1}^{N} \sum_{k=1}^{\infty} (T \phi_n, \epsilon_k) (K^* U_N \phi_n, \epsilon_k)
\]

\[
= \sum_{n=1}^{N} \sum_{k=1}^{\infty} (\phi_n, T^* \epsilon_k) (\phi_n, s_k U_N^* f_k)
\]

\[
= \sum_{k=1}^{\infty} s_k \sum_{n=1}^{N} (U_N^* f_k, \phi_n) (T^* \epsilon_k, \phi_n)
\]

\[
= \sum_{k=1}^{\infty} s_k (U_N^* f_k, T^* \epsilon_k) = \sum_{k=1}^{\infty} s_k (T U_N^* f_k, \epsilon_k)
\]

\[
\leq \sum_{k=1}^{\infty} s_k s_k (TU^*) \leq \sum_{k=1}^{N} s_k t_k
\]

\[
\leq (\sum_{k=1}^{\infty} s_k^\frac{1}{q} (\sum_{k=1}^{\infty} t_k)^\frac{1}{q}) = \|K\|_p\|T\|_q.
\]
Now let $N$ increase to infinity to obtain $\|KT\|_1 \leq \|K\|_p \|T\|_q$. Hence
$$\|\phi_K(T)\| = \text{tr}(KT) \leq \|KT\|_1 \leq \|K\|_p \|T\|_q,$$
so $\|\phi_K\| \leq \|K\|_p$.

On the other hand, for $1 < p < \infty$, let $T = \sum_{n=1}^{\infty} s_n^{p/q} (e_n \otimes f_n^*)$, then
$$\begin{align*}
\phi_K(T) &= \text{tr} \left( \sum_{n=1}^{\infty} s_n^p (f_n \otimes f_n^*) \right) = \sum_{n=1}^{\infty} s_n^p \\
&= \left( \sum_{n=1}^{\infty} s_n^{p/q} \right)^{p/q} \left( \sum_{n=1}^{\infty} (s_n^{p/q})^{q/p} \right)^{1/q} = \|K\|_p \|T\|_q.
\end{align*}$$
So $\|\phi_K\| = \|K\|_p$. If $p = 1$, let $T_N = \sum_{n=1}^{N} e_n \otimes f_n^*$. Then
$$\phi_K(T_N) = \text{tr} \sum_{n=1}^{N} s_n (f_n \otimes f_n^*) = \sum_{n=1}^{N} s_n.$$
So $\|\phi_K\| \geq \sup \|\phi_K(T_N)\| = \|K\|_1$. And if $p = \infty$, $T = e_1 \otimes f_1^*$ suffices. $\blacksquare$

1.13 Theorem. If $1 < p \leq \infty$ and $1/p + 1/q = 1$, then the map of $C_q$ into $C_p$ given by taking $K$ to $\phi_K$ is a linear, isometric isomorphism.

Proof. By the previous theorem, we know that this map is isometric. Clearly it is linear. It must be shown to be surjective. Let $\phi$ be a continuous linear functional on $C_q$. Consider the form $\\langle x, y \rangle = \phi(x \otimes y^*)$. It is routine to verify that $\\langle \cdot, \cdot \rangle$ is linear in the first variable and conjugate linear in the second. Furthermore,
$$\\langle x, y \rangle \leq \|\phi\| \|x \otimes y^*\|_p = \|\phi\| \|x\| \|y\|.$$
Thus there is a bounded linear operator $A$ with $\|A\| \leq \|\phi\|$ so that
$$\phi(x \otimes y^*) = \langle x, y \rangle = (Ax, y) = \text{tr}(A(x \otimes y^*)).$$
By linearity, $\phi(F) = \text{tr}(AF)$ for every finite rank operator $F$.

If $A$ is not compact, then from the proof that the ideal generated by $A$ is all of $B(H)$ one can obtain orthonormal families $\{e_n, n \geq 1\}$ and $\{f_n, n \geq 1\}$ so that $(Ae_n, f_n) \geq \delta > 0$ for all $n$. Let $F_n = \sum_{i=1}^{n} e_i \otimes f_i^*$. Then
\[ n \delta \leq \sum_{k=1}^{n} (A e_n, f_n) = tr(AF_n) \]
\[ = \phi(F_n) \leq \| \phi \| \| F_n \|_p = n^{1/p} \| \phi \| \] .

Hence \( \| \phi \| \geq n^{1/p} \delta \) for all \( n \geq 1 \) which is absurd. So \( A \) is compact.

Let \( A = \sum_{n=1}^{\infty} s_n (f_n \otimes e_n^*) \), and let \( F_n = \sum_{k=1}^{n} s_n^{1/k} (e_n \otimes f_n^*) \) if \( 1 < p < \infty \) or \( F_n = \sum_{k=1}^{n} e_n \otimes f_n^* \) if \( p = \infty \). Then

\[ \phi(F_n) = tr \sum_{k=1}^{n} s_k^{1/k} (f_k \otimes f_k^*) = \sum_{k=1}^{n} s_k^{1/k} \]
\[ \leq \| \phi \| \| F_n \|_p = \| \phi \| (\sum_{k=1}^{n} s_k^{1/k})^{1/p} . \]

Hence \( (\sum_{k=1}^{n} s_k^{1/k})^{1/k} \leq \| \phi \| \) for all \( n \). Hence \( A \) belongs to \( C_q \) and \( \| A \|_q \leq \| \phi \| \). 

\[ \begin{array}{l}
1.14 \text{ Corollary. } C_2 \text{ is a Hilbert space with inner product}
\[ (K, L) = tr(L^*K). \]
\end{array} \]

\[ \begin{array}{l}
1.15 \text{ Theorem. } \text{The dual of } C_1 \text{ is } B(\mathcal{H}) \text{ given by the pairing}
\[ \phi_A(T) = tr(AT). \]
\end{array} \]

\[ \begin{array}{l}
\text{Proof. } \text{By Corollary 1.6, } AT \text{ belongs to } C_1 \text{ and } \| AT \|_1 \leq \| A \| \| T \|_1 . \text{ So by Theorem 1.3, } \| \phi_A(T) \| \leq \| A \| \| T \|_1 . \text{ Hence } \| \phi_A \| \leq \| A \| . \text{ On the other hand, if } \phi \text{ is a linear functional on } C_1, \text{ then as in the proof of Theorem 1.13, } \phi = \phi_A(T) \text{ is a bounded bilinear form given by } \phi(F) = tr(AF) \text{ for every finite rank operator, and } \| A \| \leq \| \phi \| . \text{ By Theorem 1.11, } \mathcal{F} \text{ is dense in } C_1 \text{ so } \phi = \phi_A \text{ and } \| \phi_A \| = \| A \| . \text{ } \end{array} \]

This shows that \( B(\mathcal{H}) \) is a dual space, and indeed, it is the double dual of \( K \). The weak* topology in \( B(\mathcal{H}) \) is the weakest topology in which all the functionals \( \phi_T(A) = tr(TA) \) are continuous for all \( T \) in \( C_1 \).

\[ \begin{array}{l}
1.18 \text{ Proposition. Let } A \text{ belong to } C_p, 1 \leq p < \infty \text{ and let } B \text{ belong to } C^*_p . \text{ Then } tr(AB) = tr(BA). \]
\end{array} \]

\[ \begin{array}{l}
\text{Proof. } \text{It follows from Theorems 1.12 and 1.15 that } AB \text{ and } A \text{ belong to } C_1 . \text{ So by Theorem 1.3, the computation of the trace is an absolutely }
\end{array} \]
convergent sum. Also, if \( \{\phi_k, k \geq 1\} \) is an orthonormal basis,

\[
(x, y) = \sum_{k=1}^{\infty} (x, \phi_k)(y, \phi_k)
\]

converges absolutely for every \( x \) and \( y \) in \( \mathcal{H} \). So

\[
\text{tr}(BA) = \sum_{n=1}^{\infty} (BA\phi_n, \phi_n) = \sum_{n=1}^{\infty} (A\phi_n, B^*\phi_n)
\]

\[
= \sum_{n=1}^{\infty} \sum_{k=1}^{\infty} (A\phi_n, \phi_k)(B^*\phi_n, \phi_k)
\]

\[
= \sum_{k=1}^{\infty} \sum_{n=1}^{\infty} (B\phi_k, \phi_n)(A^*\phi_k, \phi_n)
\]

\[
= \sum_{k=1}^{\infty} (B\phi_k, A^*\phi_k) = \sum_{k=1}^{\infty} (AB\phi_k, \phi_k) = \text{tr}(AB) \tag*{\blacksquare}
\]

1.17 Corollary. If \( T \) is trace class and \( S \) is invertible, then
\( \text{tr}(STS^{-1}) = \text{tr}(T) \).

We finish this chapter with a useful relationship between the strong operator topology on \( \mathcal{B}(\mathcal{H}) \) and the \( C_p \) classes.

1.18 Proposition. Let \( K \) belong to \( C_p \), \( 1 \leq p \leq \infty \). If \( T_\alpha \) is a bounded net converging to \( T \) in the strong operator topology, then \( T_\alpha K \) converges to \( TK \) in the \( C_p \) norm.

Proof. Let \( M = \sup \|T_\alpha\| \) and let \( \epsilon > 0 \) be given. Choose \( F \) finite rank such that \( \|K-F\|_p < \epsilon \). Then since the range of \( F \) is finite dimensional, \( T_\alpha F \) converges to \( TF \) in norm. So

\[
\|s_k((T-T_\alpha)F)\| \leq \|(T-T_\alpha)F\|, \quad 1 \leq k \leq \text{rank}F
\]

Hence \( \|(T-T_\alpha)F\|_p \leq (\text{rank}F)^{1/p} \|(T-T_\alpha)F\| \) tends to zero. Choose \( \alpha_0 \) so that \( \|(T-T_\alpha)F\|_p < \epsilon \) for all \( \alpha \geq \alpha_0 \). Then for \( \alpha \geq \alpha_0 \),

\[
\|TK-T_\alpha K\|_p \leq \|TK-K\|_p + \|(T-T_\alpha)F\| + \|T_\alpha(F-K)\|_p
\]

\[
< M\epsilon + \epsilon + M\epsilon = (2M+1)\epsilon \tag*{\blacksquare}
\]
Notes and Remarks.

The $C_p$ classes were introduced by von Neumann and Schatten as completions of the tensor product $\mathcal{H} \otimes \mathcal{H}$ in various norms. These were investigated in a series of papers and this material is contained in Schatten's monograph [1]. The study of ideals of Hilbert spaces was initiated at about the same time by Calkin [1]. He showed that there was a correspondence between ideals and the corresponding "ideals" of $s$-numbers. The inequalities Lemma 1.7 and Corollary 1.8 are due to Fan [1]. Theorem 1.15 on the predual of $\mathcal{B}(\mathcal{H})$ is due to Dixmier [3]. There are many extensions of these ideals, and a treatment may be found in Gohberg and Krein [1].

Exercises.

1.1 Let $T$ be a Hilbert-Schmidt operator. Let $\{e_n, n \geq 1\}$ be any orthonormal basis. Prove that

$$\|T\|_2 = \left( \sum_{n=1}^{\infty} \|T e_n\|^2 \right)^{1/2} = \left( \sum_{n=1}^{\infty} \sum_{m=1}^{\infty} \|T e_n, e_m\|^2 \right)^{1/2}.$$

1.2 Let $\mathcal{H} = L^2(0,1)$ and let $K(x,y)$ be a square integrable function on $(0,1) \times (0,1)$. Let $(Tf)(x) = \int f(y)K(x,y)dy$. Prove that $T$ belongs to $C_2$ and $\|T\|_2 = \|K\|_2$.

1.3 Prove that $C_1$ coincides with the set of products $AB$ where $A$ and $B$ belong to $C_2$.

1.4 Let $T$ belong to $C_p$, $1 \leq p < \infty$, and let $\{e_n, n \geq 1\}$ and $\{f_n, n \geq 1\}$ be arbitrary orthonormal sets. Prove that

$$\sum_{n=1}^{\infty} \|(T e_n, f_n)\|^p \leq \|T\|^p.$$

Show that this inequality is sharp. Conversely, if $T$ is any operator such that

$$\sum_{n=1}^{N} \|(T e_n, f_n)\|^p \leq M^p$$

for all finite orthonormal sets, then $T$ belongs to $C_p$ and $\|T\|_p \leq M$.

1.5 Let $T_\alpha$ be a bounded net converging to $T$ in the weak operator topology. Show that if $K$ is compact, then $KT_\alpha$ converges to $KT$ in the strong operator topology. Hence if $L$ is also compact, $KT_\alpha L$ converges to $KTL$ in norm.

1.6 Let $C$ be an operator in $C_p$, $1 \leq p < \infty$ or $K$. Prove that $C$ can be factored as $C = C_1 K$ where $C_1$ belongs to $C_p$ and $K$ is compact.
2. Triangular Algebras

Any matrix $A$ acting on $\mathcal{C}^n$ has a triangular form. That is, one can find an orthonormal basis \( \{ e_1, \ldots, e_n \} \) so that the subspaces \( N_j = \text{span} \{ e_1, \ldots, e_j \} \), \( 1 \leq j \leq n \), are all invariant for $A$. With respect to this basis, $A$ has a matrix \( (a_{ij}) \) in which $a_{ij} = 0$ if $i > j$. Also, the spectrum of $A$ is read off as \( \{ a_{jj}, 1 \leq j \leq n \} \) including multiplicity. Consider the analogue for an operator $T$ acting on a Hilbert space $\mathcal{H}$. To ask for an orthonormal basis \( \{ e_n, n \geq 1 \} \) so that $N_j = \text{span} \{ e_1, \ldots, e_j \}$ is invariant is too demanding because this forces $T$ to have lots of eigenvectors. Even fairly nice operators can fail to have eigenvectors. So instead, we ask for a (linearly ordered) chain of (closed) invariant subspaces of $T$. Even this may not be possible for all operators.

2.1. A nest is a chain $\mathcal{N}$ of closed subspaces of a Hilbert space $\mathcal{H}$ containing $\{0\}$ and $\mathcal{H}$ which is closed under intersection and closed span.

In other words, a nest is a chain of subspaces which is complete with respect to the natural lattice operations on the lattice of all subspaces of a Hilbert space. The set $\text{Lat}T$ of invariant subspaces of an operator $T$ is always a complete lattice. So there is no loss in considering only nests instead of arbitrary chains. Give any chain $\mathcal{C}$ of invariant subspaces of $T$, one can always extend it to a maximal chain of invariant subspaces. This follows from Zorn's Lemma and the fact that the union of an increasing family of chains of invariant subspaces is also a chain of invariant subspaces. This largest chain is necessarily complete, as the completion is also an invariant chain.

Given an orthonormal basis for $\mathcal{C}^n$, one defines the algebra of all upper triangular matrices. By analogy, one makes the following definition.

The triangular algebra or nest algebra $\mathcal{T}(\mathcal{H})$ is the set of all operators $T$ such that $TN \subseteq N$ for every element $N$ in $\mathcal{H}$.

2.2 Proposition. $\mathcal{T}(\mathcal{H})$ is a weak operator closed subalgebra of $B(\mathcal{H})$.

Proof. It is clear that $\mathcal{T}(\mathcal{H})$ is a linear space containing the scalar operators. If $A$ and $B$ belong to $\mathcal{T}(\mathcal{H})$, and $N$ belongs to $\mathcal{H}$, then

\[
AB(N) \subseteq A(N) \subseteq N.
\]

So $AB$ belongs to $\mathcal{T}(\mathcal{H})$. Finally, if $A_\alpha$ belong to $\mathcal{T}(\mathcal{H})$ and $A$ is a weak limit point of $A_\alpha$ then for every $N$ in $\mathcal{H}$, $x$ in $N$ and $y$ in $N^\perp$,
0 = \lim(A_n x, y) = (Ax, y).

Thus AN is contained in N, and A belongs to \(\tau(\mathcal{H})\).

Before proceeding, consider some examples of nests.

2.3 Example. Let \(P_n\) be an increasing sequence of finite dimensional subspaces such that their union is dense in \(\mathcal{H}\). Then \(\mathcal{P} = \{0\}, P_n, n \geq 1, \mathcal{H}\) is a complete nest. \(\tau(\mathcal{P})\) consists of all operators which have a block upper triangular matrix with respect to \(\mathcal{P}\). The nest \(\mathcal{P}\) is maximal exactly when \(\dim P_n = n\) for all \(n\).

2.4 Example. Let \(\mathcal{H} = L^2([0,1])\) with Lebesgue measure. For each \(t\) in \([0,1]\), let \(N_t\) consist of all functions \(f\) in \(L^2([0,1])\) such that \(f(x) = 0\) a.e. on \([t,1]\). Then \(\mathcal{H} = \{N_t: 0 \leq t \leq 1\}\) is a “continuous” nest. (See Section 2.7).

2.5 Example. Let \(\mathcal{H} = L^2((0,1)^2)\) be the space of Lebesgue square integrable functions on the unit square. Analogous to the preceding example, let \(M_t\) be the set of functions supported on \([0,t] \times [0,1]\). Then \(\mathcal{M} = \{M_t, 0 \leq t \leq 1\}\) is a continuous nest. It is maximal (Proposition 2.10) but it is different from Example 2.4 in an essential way (Chapter 7).

2.6 Example. Let \(\mu\) be counting measure on the set of rational numbers \(\mathbb{Q}\). Let \(\mathcal{H} = l^2(\mathbb{Q}) = L^2(\mu)\). For each \(t\) in \(\mathbb{R}\), let \(Q^+_t = \{f \in l^2(\mathbb{Q}) : f(q) = 0\ \text{for} \ q > t\}\) and \(Q^-_t = \{f \in l^2(\mathbb{Q}) : f(q) = 0\ \text{for} \ q \geq t\}\). Note that if \(t\) is irrational, then \(Q^-_t = Q^+_t\). But if \(t\) belongs to \(\mathbb{Q}\), then \(Q^+_t \otimes Q^-_t = \text{span} \{\delta_t\} \) where \(\delta_t\) is the characteristic function of \(t\). Set \(Q_{-\infty} = \{0\}\) and \(Q_{+\infty} = \mathcal{H}\). Then \(\mathcal{Q} = \{Q^+_t : -\infty \leq t \leq +\infty\}\) is a nest. The set \(\{\delta_t : t \in \mathbb{Q}\}\) is an orthonormal basis for \(\mathcal{H}\). This nest is “atomic” (Section 2.7) because the space is spanned by the gaps between adjacent elements of the nest.

2.7. Given a collection \(\{M_\alpha\}\) of subspaces of a Hilbert space, \(\vee M_\alpha\) denotes the closed linear span and \(\wedge M_\alpha\) denotes intersection. This makes the set of subspaces of \(\mathcal{H}\) into a lattice. A nest is just a complete, totally ordered sublattice. For \(N\) belonging to a nest \(\mathcal{N}\), define

\[N_- = \vee\{N' \in \mathcal{H} : N' < N\}\]

and
\[ N_+ = \bigwedge \{ N' \in \mathcal{N} : N' > N \} \]

It is easy to see that \( N_+ \) is the immediate predecessor to \( N \) if there is one. Otherwise \( N_- = N \). If \( N_- \neq N \), then \( N = (N_-)_+ \) is the immediate successor of \( N_- \).

The subspaces \( N \ominus N_- \) are called the atoms of \( \mathcal{N} \). If the atoms of \( \mathcal{N} \) span \( \mathcal{N} \), then \( \mathcal{N} \) is atomic (e.g. Examples 2.3 and 2.6). If there are no atoms, \( \mathcal{N} \) is called continuous (e.g. Examples 2.4 and 2.5).

The algebras \( \mathcal{T}(\mathcal{N}) \) contain an abundance of operators, and this will be used to prove reflexivity. Given an algebra \( \mathcal{A} \), the lattice of all invariant subspaces of \( \mathcal{A} \) is denoted \( \text{Lat} \mathcal{A} \). Similarly, if \( \mathcal{L} \) is a lattice of subspaces, then \( \text{Alg} \mathcal{L} \) denotes the algebra of all operators leaving each element of \( \mathcal{L} \) invariant. The lattice \( \mathcal{L} \) is reflexive if \( \mathcal{L} = \text{Lat} \text{Alg} \mathcal{L} \); and an algebra \( \mathcal{A} \) is reflexive if \( \mathcal{A} = \text{Alg} \text{Lat} \mathcal{A} \). Clearly, \( \mathcal{T}(\mathcal{N}) \) is reflexive. It turns out that \( \mathcal{N} \) is also reflexive.

2.8 Lemma. Let \( N \) belong to \( \mathcal{N} \). Then every operator of the form \( T = P(N_+)TP(N)^\perp \) belongs to \( \mathcal{T}(\mathcal{N}) \).

Proof. Let \( N' \) belong to \( \mathcal{N} \). Then either \( N' \geq N_+ \) or \( N' \leq N \). In the first case, \( P(N')P(N_+) = 0 \) so \( P(N')TP(N') = 0 \). In the second case \( P(N)^\perp P(N') = 0 \) so \( P(N')TP(N') = 0 \). Thus \( N' \) is invariant for \( T \).

2.9 Theorem. \( \text{Lat} \mathcal{T}(\mathcal{N}) = \mathcal{N} \).

Proof. Let \( M \) be an invariant subspace for \( \mathcal{T}(\mathcal{N}) \) and let \( N \) be the least element of \( \mathcal{N} \) containing \( M \). Let \( N' \) be any other element of \( \mathcal{N} \) with \( N' < N \). Since \( M \nsubseteq N' \), there is a vector \( x \) in \( M \) such that \( P(N')x \neq 0 \). Let \( y \) be any vector in \( N'_+ \), and let \( T \) be an operator of the form \( T = P(N'_+)TP(N')^\perp \) such that \( TP(N')^\perp x = y \). By Lemma 2.8, \( T \) belongs to \( \mathcal{T}(\mathcal{N}) \). Thus \( y = Tx \) belongs to \( M \). Hence

\[ M \supseteq \bigvee \{ N'_+ : N' < N \} = N \]

(To verify this identity, consider two cases, \( N = N_- \) and \( N = (N_-)_+ \).)

Thus \( M = N \) belongs to \( \mathcal{N} \).

A nest is maximal if it is not contained in any larger nest.

2.10 Proposition. A nest is maximal if and only if all its atoms are one dimensional.
Proof. Necessity is clear. Suppose that \( \mathcal{N} \) is a nest in which all atoms are one dimensional. Let \( M \) be a subspace such that for every \( N \) in \( \mathcal{N} \), either \( N \leq M \) or \( N > M \). Let

\[
N_0 = \bigvee \{ N \in \mathcal{N} : N \leq M \}
\]

and

\[
N_1 = \bigwedge \{ N \in \mathcal{N} : N \geq M \}.
\]

Clearly, \( N_0 \leq M \leq N_1 \). Also, if \( N \) belongs to \( \mathcal{N} \), either \( N \leq N_0 \) or \( N \geq N_1 \). If \( N_0 = N_1 \), then \( M = N_0 \) belongs to \( \mathcal{N} \). If \( N_0 \neq N \), then

\( N_1 \ominus N_0 \) is an atom of \( \mathcal{N} \) and hence is one dimensional. So \( M \) equals \( N_0 \) or \( N_1 \) and thus belongs to \( \mathcal{N} \). (From this, it follows that \( N_0 = N_1 \) after all.) So \( \mathcal{N} \) cannot be expanded to a larger nest.

2.11. A subspace \( N \) is invariant for \( T \) exactly when \( N^\perp \) is invariant for \( T^* \). Thus it follows that \( \mathcal{T}(\mathcal{N})^* = \mathcal{T}(\mathcal{N}^\perp) \) where \( \mathcal{N}^\perp \) is the nest \( \{ N^\perp : N \in \mathcal{N} \} \). The intersection \( \mathcal{D}(\mathcal{N}) = \mathcal{T}(\mathcal{N}) \cap \mathcal{T}(\mathcal{N})^* \) is the diagonal of \( \mathcal{T}(\mathcal{N}) \). This is the weakly closed, self-adjoint algebra (von Neumann algebra) of all operators \( T \) which leave \( \mathcal{N} \) and \( \mathcal{N}^\perp \) invariant. Thus if \( N \) belongs to \( \mathcal{N} \),

\[
TP(N) = P(N)TP(N) = (P(N)T^*P(N))^* = (T^*P(N))^* = P(N)T^*.
\]

Conversely, if \( T \) commutes with \( P(N) \) for all \( N \) in \( \mathcal{N} \), then

\[
TP(N) = P(N)TP(N) \quad \text{and} \quad TP(N)^\perp = P(N)^\perp TP(N)^\perp
\]

so \( T \) belongs to \( \mathcal{D}(\mathcal{N}) \). Thus \( \mathcal{D}(\mathcal{N}) = \mathcal{N}'' \) is the commutant of \( \{ P(N) : N \in \mathcal{N} \} \).

One also defines the core of \( \mathcal{T}(\mathcal{N}) \) to be the von Neumann algebra generated by \( \{ P(N) : N \in \mathcal{N} \} \). By the Double Commutant Theorem, this is just the commutant of \( \mathcal{D}(\mathcal{N}) \) and will be denoted by \( \mathcal{N}'' \). Note that \( \mathcal{N}'' \) is abelian, and hence is the centre of \( \mathcal{D}(\mathcal{N}) \).

A vector \( x \) is a cyclic for a von Neumann algebra \( \mathcal{A} \) provided \( \mathcal{A}x \) is dense in \( \mathcal{N} \). A vector \( x \) is separating for a von Neumann algebra \( \mathcal{A} \) provided \( Ax = 0 \) implies \( A = 0 \) for \( A \) in \( \mathcal{A} \).

2.12 Proposition. Let \( \mathcal{M} \) be an abelian von Neumann algebra on a separable Hilbert space. Then \( \mathcal{M}'' \) has a cyclic vector \( x \). Hence \( x \) is a separating vector for \( \mathcal{M} \).

Proof. Let \( x \) be any vector in \( \mathcal{N} \). Let \( \mathcal{N}_x \) denote the closure of \( \{ Ax : A \in \mathcal{M}' \} \), and let \( P_x \) be the orthogonal projection onto \( \mathcal{N}_x \). Since \( \mathcal{N}_x \) is invariant for \( \mathcal{M}' \), \( P_x \) commutes with \( \mathcal{M}' \) and thus belongs to \( \mathcal{M} \). If \( E \) is a
projection in $\mathcal{M}$, then $A(Ex) = E(Ax)$ for $A$ in $\mathcal{M}$. Thus $\mathcal{H}_{Ex} = E\mathcal{H}_x$ and $P_{Ex} = EP_x$.

Let $\{x_n\}$ be a maximal family of unit vectors (necessarily countable) such that $P_n = P_{x_n}$ are pairwise orthogonal (provided by an application of Zorn’s lemma). If $P = \sum P_n$ is not the identity, one could take any unit vector $x = P^\perp x$ and obtain a nonzero projection $P_x \leq P^\perp$ which extends $\{x_n\}$. Thus $\sum P_n = I$. Set $x = \sum_{n \geq 1} 2^{-n} x_n$. Then $\mathcal{H}_x$ contains $2^n P_n x = x_n$ for all $n \geq 1$. Hence $\mathcal{H}_x$ contains $\sum \mathcal{H}_{x_n} = \mathcal{H}$, and so $x$ is cyclic for $\mathcal{M}'$.

If $T$ belongs to $\mathcal{M}$, then

$$\mathcal{H}_{T x} = \langle ATz : A \in \mathcal{M}' \rangle = \langle TAx : A \in \mathcal{M}' \rangle = \overline{T \mathcal{H}_x} = \overline{\text{Ran } T}.$$

Thus if $Tx = 0$, one has $\text{Ran } (T) = \{0\}$ and thus $T = 0$. So $x$ is a separating vector for $\mathcal{M}$.

The nest $\mathcal{N}$ has an order $<$ given by containment. So $(\mathcal{H}, <)$ is a topological space when endowed with the order topology. The set $P(\mathcal{N}) = \{P(N) : N \in \mathcal{N}\}$ is ordered as a subset of the positive operators on $\mathcal{H}$, and it is a topological space when endowed with the strong operator topology.

**2.13 Theorem.** Let $\mathcal{N}$ be a nest. Then the natural map taking $N$ to $P(N)$ is an order preserving homeomorphism of the compact Hausdorff space $(\mathcal{H}, <)$ onto $(P(\mathcal{N}), \preceq)$. If $\mathcal{N}$ has a unit separating vector $x$, then the map $\Phi_x(N) = (P(N)x, x)$ is an order preserving homeomorphism of $(\mathcal{H}, <)$ onto a compact subset of $[0,1]$.

**Proof.** First it will be shown that $P(\mathcal{N}) = \{P(N) : N \in \mathcal{N}\}$ is compact in the strong operator topology. Let $\overline{P(\mathcal{N})}$ denote the weak operator closure, which is compact since it is bounded. Let $P_\alpha = P(N_\alpha)$ be a net of projections converging weakly to an operator $E$. By the Double Commutant Theorem, $E$ is a positive contraction in $\mathcal{M}''$. Let $N_0$ be the least element of $\mathcal{N}$ such that $P(N_0) \geq E$. Let $N$ be any element of $\mathcal{N}$ with $N < N_0$. By the minimality of $N_0$, there is a unit vector $x$ in $N_0 \ominus N$ such that $Ex \neq 0$. Thus $(Ex, x) > 0$. Hence there is an $\alpha_0$ so that $(P_\alpha x, x) > 0$ for all $\alpha \geq \alpha_0$, and consequently $P_\alpha \geq P(N_\alpha)$. Similarly, if $N' \in \mathcal{N}$ and $N' > N_0$ let $x$ be any unit vector in $N' \ominus N_0$. So there is an $\alpha_0$ so that $(P_\alpha x, x) < 1$ for all $\alpha \geq \alpha_0$. Hence $P_\alpha \leq P(N'_-)$. Therefore, for every $N$, $N'$ in $\mathcal{N}$ with $N < N_0 < N'$ there is an $\alpha_0$ so that $P_\alpha x = Ex = P(N_0)x$ for every $x$ in $N_+ \oplus (N'_-)$. The union of these
subspaces is dense in $N_0 \oplus N_0^\perp = \mathcal{H}$. It follows that $P_o$ converges to $P(N_0)$ in the strong operator topology. This shows that $P(\mathcal{H})$ is weak operator closed, hence compact, and that the strong operator topology coincides with the weak operator topology on $P(\mathcal{H})$. So it is compact in the strong operator topology as well.

The map taking $P(N)$ to $N$ is an order preserving bijection of a compact Hausdorff space onto another Hausdorff space. To show that it is continuous, it suffices to show that $\{P(N): N < N_0\}$ and $\{P(N): N > N_0\}$ are open. If $x$ is a vector, $\|P(N)x\|$ is an increasing function of $N$ which is strong operator continuous, thus $\{P(N): \|P(N)x\| < 1\}$ and $\{P(N): \|P(N)x\| > 1\}$ are open. Such sets separate the points of $\mathcal{H}$. Hence $(P(\mathcal{H}), <)$ and $(\mathcal{H}, <)$ are homeomorphic.

If $x$ is a separating vector, the map $\Phi_x$ is strongly continuous and strictly increasing on $\mathcal{H}$. Thus $\Phi_x(\mathcal{H})$ is a compact subset of $[0,1]$. The topology on $[0,1]$ is just the order topology, so this is a homeomorphism.

2.14 Example. Now one can talk about the order type of a nest by representing it as a compact subset of $[0,1]$. Consider the examples 2.3 - 2.6. Example 2.3 has order type $\omega = \aleph_0 \cup \{\infty\}$. Example 2.4 and 2.5 have order type $[0,1]$ and $x(t) = 1$ is a separating vector. In 2.4, it is also a cyclic vector for $\mathcal{M}'' = \mathcal{M}'$. But in 2.5, $\mathcal{M}'$ is much bigger than $\mathcal{M}''$ and $\mathcal{M}''$ has no cyclic vector. Example 2.6 is a bit more complicated. Let $a_r$ be non-zero complex numbers for each $r$ in $\mathcal{Q}$ such that $\sum |a_r|^2 = 1$. Then $x = \sum a_r \delta_r$ is a separating and cyclic vector for $\mathcal{Q}'' = \mathcal{Q}'$. The map $\Phi_x$ takes $\mathcal{Q}$ onto a compact subset of $[0,1]$. For each $r$ in $\mathcal{Q}$, $t_{r-} = \Phi_x(Q_{r-})$ is strictly less than $t_{r+} = \Phi_x(Q_{r+})$. So there is an interval $(t_{r-}, t_{r+})$ in $[0,1] \Phi_x(\mathcal{Q})$. This set of "gaps" is dense since the atoms are dense in the order of $\mathcal{Q}$. Thus $\Phi_x(\mathcal{Q})$ is a perfect set with no interior and must be order homeomorphic to the Cantor set.

If $N_1 < N_2$ in $\mathcal{H}$, the subspace $E = N_2 \ominus N_1$ is called an interval of $\mathcal{H}$. The significance of intervals is due in part to the following two propositions.

2.15 Proposition. Let $E$ be an interval of $\mathcal{H}$. Then the map $\Phi_E$ of $T(\mathcal{H})$ into $B(E)$ given by

$$\Phi_E(T) = P(E)\mathcal{T}|E$$

is an algebra homomorphism onto $T(\mathcal{H}_E)$ where $\mathcal{H}_E$ is the nest $\{N \cap E: N \in \mathcal{H}\}$. This map is continuous in all the natural topologies on $B(\mathcal{H})$. 
Proof. Let $E = N_2 \ominus N_1$ for $N_1, N_2$ in $\mathcal{H}$ and let $P = P(N)$. If $N$ is invariant for $T$, then \( TP(N) = P(N)TP(N) \) and \( P(N)^\perp T = P(N)^\perp TP(N)^\perp \). Thus for $T_1, T_2$ in $\mathcal{T}(\mathcal{H})$ one has
\[
(P_2 - P_1)T_1T_2(P_2 - P_1) = P_2(P_1^\perp T_1)(T_2^\perp P_2)P_1^\perp
\[
= P_2(P_1^\perp T_1 P_1)(P_2 T_2^\perp P_2)P_1
\[
= P(E)T_1P(E)T_2P(E)
\]
Hence \( \Phi_E(T_1 T_2) = \Phi_E(T_1)\Phi_E(T_2) \). As \( \Phi_E \) is linear, it is an algebra homomorphism. Clearly, \( \|\Phi_E\| \leq 1 \) so \( \Phi_E \) is continuous.

For $N$ in $\mathcal{H}$ and $T$ in $\mathcal{T}(\mathcal{H})$, $\Phi_E(T)$ takes $\mathcal{H} \cap E$ into $P(E)N = N \cap E$. So $\Phi_E(T)$ belongs to $\mathcal{T}(\mathcal{H}_E)$. On the other hand, if $A$ belongs to $\mathcal{T}(\mathcal{H}_E)$, let $T = AP(E)$). Clearly, $T$ belongs to $\mathcal{T}(\mathcal{H})$ and $\Phi_E(T) = A$. So $\Phi_E$ is surjective. ■

2.18 Theorem. Let $\mathcal{A}$ be an algebra of operators, and let $E$ be a subspace such that $\Phi_E(A) = P(E)A \mid E$ is an algebra homomorphism. Then there are invariant subspaces $N_1$ and $N_2$ for $\mathcal{A}$ such that $E = N_2 \ominus N_1$. In particular, if $\mathcal{A} = \mathcal{T}(\mathcal{H})$, then $E$ is an interval of $\mathcal{H}$.

Proof. Let $N_2$ be the smallest invariant subspace of $\mathcal{A}$ containing $E$. Thus $N_2$ is the closure of $\{Ae : A \in \mathcal{A}, e \in E \}$. Set $N_1 = N_2 \ominus E$. It suffices to show that $N_1$ is invariant for $\mathcal{A}$. Now if $A$ and $B$ belong to $\mathcal{A}$,
\[
0 = \Phi_E(AB) - \Phi_E(A)\Phi_E(B)
\[
= P(E)ABP(E) - P(E)AP(E)BP(E)
\[
= P(E)AP(E)^\perp BP(E)
\]
Since the ranges of $BP(E)$ spans $N_2$ as $B$ runs over $\mathcal{A}$, it follows that the ranges of $P(E)^\perp BP(E)$ spans $N_1$. Thus $P(E)AP(N_1) = 0$ for all $A$ in $\mathcal{A}$. Hence
\[
AP(N_1) = P(E)^\perp P(N_2)AP(N_1) = P(N_1)AP(N_1)
\]
So $N_1$ is invariant.

In the case of nest algebra, Theorem 1.10 shows that $N_1$ and $N_2$ belong to $\mathcal{H}$. So $E$ is an interval of $\mathcal{H}$. ■

2.17. The atomic part of the diagonal of $\mathcal{T}(\mathcal{H})$ is $D_a = \sum_{A_o \in A} B(A_o)$ where $A = \{A_o\}$ is the set of atoms of $\mathcal{H}$. The map $\Delta(T) = \sum P(A_o)TP(A_o)$ is a contractive projection of $\mathcal{B}(\mathcal{H})$ onto $D_a$. By Proposition 2.15, $\Delta$ is multiplicative on $\mathcal{T}(\mathcal{H})$. 

Triangular Algebras
Notes and Remarks.

A class of triangular algebras was introduced by Kadison and Singer [1]. This class contained nest algebras with maximal nests and many algebras that are not even norm closed. The order type of a nest, and the diagonal for nest algebra are first used here. The notion of a nest was introduced by Ringrose [1] in connection with triangular forms for compact operators. Proposition 2.10 is proved in that paper. In a sequel, Ringrose [3], Lemma 2.8 and Theorem 2.9 are proven as is Proposition 2.15. Theorem 2.16 is due to Sarason [1]. The notions of $Alg$, $Lat$, and reflexive algebras are due to Halmos.

Exercises.

2.1 Let $L$ be any collection of subspaces of $H$. Prove that $Alg L$ is a weakly closed, unital algebra.

2.2 Given a compact subset $\omega$ of $[0,1]$, construct a nest $\mathcal{N}$ of order type $\omega$.

2.3 Prove that every von Neumann algebra is the norm closure of the span of its projections. Hence prove that every von Neumann algebra is reflexive, and identify its invariant subspace lattice.

2.4 Let $T$ belong to $\mathcal{T}(\mathcal{N})$, and let $\Delta(T)$ be the projection of section 2.17. Show that the spectrum of $\Delta(T)$ is a subset of $\sigma(T)$. 
3. Triangular Forms for Compact Operators

The starting point is the existence of proper invariant subspaces for compact operators. The proof presented here is old fashioned, but illustrates how one can lift the finite dimensional triangular forms to the compact operator case.

3.1 Theorem. Let $K$ be a compact operator on a Hilbert space $\mathcal{H}$. Then $K$ has a proper invariant subspace.

Proof. Let $P_n$ be any increasing sequence of finite rank projections increasing to the identity. Then $K_n = P_nKP_n$ converges to $K$ in norm. The restriction of $K_n$ to $P_n\mathcal{H}$ is a finite rank operator and thus can be put in triangular form with respect to some chain $\{P_{n,j}, 0 \leq j \leq \text{rank } P_n \}$ so that $\text{rank } P_{n,j} = j$. Fix a unit vector $x = P_1x$. Let $j_n$ be the least integer such that $(P_{n,j_n}x, x) \geq \frac{1}{2}$. Set $Q_n = P_{n,j_n}$ and $Q_n^- = P_{n,j_n-1}$.

The set $\{Q_n, n \geq 1\}$ is bounded, so there is a subsequence which converges in the weak operator topology to an operator $Q$. Likewise on a sub-subsequence, one has $Q_n^-$ converging weakly to an operator $Q^-$. Relabel this subsequence so that

$$Q = w\lim Q_n \quad \text{and} \quad Q^- = w\lim Q_n^-.$$ 

Then $0 \leq Q^- \leq Q \leq I$. Furthermore, since $Q_n - Q_n^-$ are rank one, it follows that $Q - Q^-$ has rank at most one. Also,

$$(Qx, x) = \lim (Q_nx, x) \geq \frac{1}{2}$$

and

$$(Q^-x, x) = \lim (Q^-nx, x) \leq \frac{1}{2}.$$ 

Thus $Q \neq 0$, $Q^- \neq I$, and $Q - Q^-$ is rank one. So either $Q$ or $Q^-$ is neither 0 nor $I$. We shall suppose that $Q \neq I$.

Since $K$ is compact, $\lim_{n \to \infty} KQ_n x = KQx$ exists in norm for every vector $x$ (Exercise 1.5). Thus since $K = \lim_{n \to \infty} K_n$ and $(I - Q_n)K_nQ_n = 0$, 

31
\[
\lim_{n \to \infty} Q_n K Q x = K Q x - \lim_{n \to \infty} (I - Q_n)(K Q x - K_n Q_n x) = K Q x
\]

Thus this limit exists in norm. So
\[
K Q x = \lim_{n \to \infty} Q_n K Q x = Q K Q x.
\]

From this, it follows that \(K\) carries the range \(\text{Ran}(Q)\) of \(Q\) into the eigenspace \(N = \text{ker}(Q-I)\). Hence any subspace \(M\) such that \(N \subseteq M \subseteq \text{Ran}(Q)\) is invariant for \(K\). As \(Q \neq I\), \(N\) is not all of \(\mathcal{H}\); and as \(Q \neq 0\), \(\text{Ran}(Q)\) is not zero. Thus there is a proper subspace \(M\) of this form. \(\blacksquare\)

### 3.2 Corollary

Let \(K\) be a compact operator on a Hilbert space \(\mathcal{H}\). Then there is a maximal nest \(\mathcal{N}\) of invariant subspaces of \(K\).

**Proof.** Apply Zorn’s lemma to obtain a maximal chain \(\mathcal{N}\) of invariant subspaces of \(K\). Since \(\text{Lat} K\) is a complete lattice, \(\mathcal{N}\) is complete and thus is a nest. By Proposition 2.10, it is enough to verify that \(\text{dim}(N \oplus N_-) \leq 1\) for all \(N\) in \(\mathcal{N}\). If, on the contrary, \(\text{dim}(N \oplus N_-) \geq 2\), let \(K_0 = P(E)K|E\) where \(E = N \oplus N_-\). As \(K_0\) is compact, Theorem 3.1 provides a proper closed subspace \(M\) of \(E\) invariant for \(K_0\). But then \(N_- \oplus M\) is invariant for \(K\) and is intermediate to \(N_-\) and \(N\). This contradicts the maximality of \(\mathcal{N}\) in \(\text{Lat} K\). Hence all atoms are one dimensional and \(\mathcal{N}\) is a maximal nest. \(\blacksquare\)

### 3.3

As in the matrix case, one can read off information about the spectrum of a compact operator from its triangular form. Let \(K\) be compact and let \(\mathcal{N}\) be a maximal nest of invariant subspaces of \(K\). Let \(A = \{A_\alpha\}\) be the (one-dimensional) atoms of \(\mathcal{N}\). By Proposition 2.15, \(\Phi_\alpha(T) = P(A_\alpha)T|A_\alpha\) is an algebra homomorphism of \(\tau(\mathcal{N})\). In this case, \(\Phi_\alpha(T)\) is just a scalar number so \(\Phi_\alpha\) is a multiplicative linear functional of \(\tau(\mathcal{N})\). It follows that \(\lambda_\alpha = \Phi_\alpha(T)\) belongs to the spectrum of \(T\) as an element of \(\tau(\mathcal{N})\). For otherwise
\[
1 = \Phi_\alpha((T-\lambda_\alpha I)(T-\lambda_\alpha I)^{-1}) = \Phi_\alpha(T-\lambda_\alpha I)(T-\lambda_\alpha I)^{-1} = 0
\]
which is absurd. In general, the spectrum of \(T\) in \(\tau(\mathcal{N})\) is greater than \(\sigma(T)\). However, in the case of a compact operator, more can be said.

### 3.4 Ringrose’s Theorem

Let \(K\) be a compact operator. Let \(\mathcal{N}\) be a maximal nest of invariant subspaces for \(K\), and let \(A = \{A_\alpha\}\) be the atoms of \(\mathcal{N}\). Then \(\sigma(K) = \sigma_{\tau(\mathcal{N})}(K) = \{0\} \cup \{\Phi_\alpha(K) : A_\alpha \in A\}\) and the non-zero values are repeated according to their algebraic multiplicity.
First, we need a lemma. A partition of a nest $\mathcal{N}$ is a finite set $E_{1}, \ldots, E_{s}$ of pairwise orthogonal intervals of $\mathcal{N}$ such that $\sum_{i=1}^{s} E_{i} = \mathcal{N}$. A partition is always obtained from a finite subnest \( \{0\} = M_{0} < M_{1} < \ldots < M_{s} = \mathcal{N} \) of $\mathcal{N}$ by $E_{i} = M_{i} \ominus M_{i-1}$.

3.5 Lemma. Let $\mathcal{N}$ be a nest, and let $K$ be a compact operator in $\mathcal{T}(\mathcal{N})$. Given $\epsilon > 0$, there is a partition $E_{1}, \ldots, E_{s}$ of $\mathcal{N}$ so that for each $1 \leq i \leq s$, either $E_{i}$ is an atom or $\|P(E_{i})K(P(E_{i}))\| < \epsilon$.

Proof. Let $N \neq \{0\}$ belong to $\mathcal{N}$. If $N = N_{\omega}$, then the net $P(N_{\alpha})$ for $\{N_{\alpha} \in \mathcal{N} : N_{\alpha} < N\}$ indexed by itself converges to $P(N)$ in the strong* operator topology. Hence by Proposition 1.18, $(P(N) - P(N_{\alpha}))K$ converges to zero in norm. Thus there is a subspace $L(N) < N$ in $\mathcal{N}$ so that

$$\|P(N \ominus L(N))K(P(N \ominus L(N)))\| < \epsilon .$$

If $N \neq N_{\omega}$, set $L(N) = N_{\omega}$. Then $N \ominus L(N)$ is an atom. Similarly, if $N \neq \mathcal{N}$, one can find $U(N) > N$ in $\mathcal{N}$ so that either $U(N) \ominus N$ is an atom or

$$\|P(U(N) \ominus N)K(P(U(N) \ominus N))\| < \epsilon .$$

Let $O_{N} = \{N_{i} \in \mathcal{N} : N_{i} < N' < U(N)\}$ for $N$ in $\mathcal{N}$ with the exceptions $O_{\{0\}} = \{N_{i} \in \mathcal{N} : N' < U(\{0\})\}$ and $O_{\mathcal{N}} = \{N_{i} \in \mathcal{N} : N' > L(\mathcal{N})\}$. These sets are open intervals of $\mathcal{N}$ in the order topology which cover $\mathcal{N}$. By Theorem 2.13, $\mathcal{N}$ is compact. Thus there is a finite subcover $O_{N_{1}}, \ldots, O_{N_{k}}$. The set $\{N_{i}, L(N_{i}), U(N_{i}), 1 \leq i \leq k\}$ in its natural order is a finite nest $\{0\} = M_{0} < M_{1} < \ldots < M_{s} = \mathcal{N}$. Let $E_{i} = M_{i} \ominus M_{i-1}$. As each $E_{i}$ is dominated by one of the intervals $N_{i} \ominus L(N_{i})$ or $U(N_{i}) \ominus N_{i}$, it follows that $E_{i}$ is either an atom or $\|P(E_{i})K(P(E_{i}))\| < \epsilon$.

Proof of Theorem 3.4. Suppose that $\lambda$ does not belong to the set $\Lambda = \{0\} \cup \{\Phi_{\alpha}(K) : A_{\alpha} \in A\}$. It must be shown that $K - \lambda I$ is invertible. Let $\epsilon = |\lambda|/2$ and apply Lemma 3.5. One obtains a finite subnest $\{0\} = M_{0} < M_{1} < \ldots < M_{s} = \mathcal{N}$ and intervals $E_{i} = M_{i} \ominus M_{i-1}$ such that either $\|P(E_{i})K(P(E_{i}))\| < \epsilon$ or $E_{i}$ is an atom. In the latter case $P(E_{i})K(P(E_{i})) = \lambda_{i}P(E_{i})$ and $\lambda_{i}$ belongs to $\Lambda$.

Let $(K_{ij})$ be the $s \times s$ upper triangular matrix form of $K$ with respect to this finite nest $\mathcal{N}$. The diagonal entries are $K_{ii} = P(E_{i})K[|E_{i}|]$. By construction, $K_{ii} - \lambda_{i}I_{i}$ is invertible (where $I_{i} = I[|E_{i}|]$). Hence $K - \lambda I$ is invertible. To see this, let $T$ be the $s \times s$ diagonal matrix with entries $T_{ii} = (K_{ii} - \lambda_{i}I_{i})^{-1}$. Then $T(K - \lambda I)$ is an upper triangular $s \times s$ matrix with diagonal entries $I_{i}$. In other words, $T(K - \lambda I) = I + N$ where $N$ is strictly upper triangular. Since $N^{s} = 0$, $(I + N)^{-1} = \sum_{K=0}^{s-1} N^{K}$ exists and is upper triangular. Thus $ST$ is $(K - \lambda I)^{-1}$. 

Note that \((K-\lambda I)^{-1}\) belongs to \(T(M)\). This is still the case if \(M\) is replaced by a larger finite nest containing any given \(N\) in \(\mathcal{N}\). That means \(N\) is invariant for \((K-\lambda I)^{-1}\). As \(N\) is arbitrary, \((K-\lambda I)^{-1}\) belongs to \(T(M)\).

Now suppose that \(\lambda \neq 0\) belongs to \(\Lambda\) and occurs \(n\) times. Repeat the above construction to obtain a finite nest \(\mathcal{M}\) with intervals \(E_1, \ldots, E_s\) so that \(K\) has an upper triangular form for \((K_{ij})\) where either \(K_{ii} = \lambda I_i\) or \(K_{ii} - \lambda I\) is invertible. The former situation occurs exactly \(n\) times, say for \(i\) in a set \(X\). Let \(C\) be an oriented circle centered at \(\lambda\) so that \(\sigma(K_{ii})\) is disjoint from \(C \cup \text{int} C\) unless \(i\) belongs to \(X\). For \(x\) in \(C\), \((zI-K)^{-1}\) is an \(s \times s\) upper triangular form with diagonal entries \((zI_i - K_{ii})^{-1}\). Thus one can compute the Riesz indempotent for \(K\) and \(\{\lambda\}\) as

\[
P_{\lambda} = \frac{1}{2\pi i} \int_C (zI - K)^{-1} dz .
\]

This has matrix entries given by integration of the matrix entries of \((zI-K)^{-1}\). So it is upper triangular, and its diagonal entries are

\[
(P_{\lambda})_{ii} = \frac{1}{2\pi i} \int_C (zI_i - K_{ii})^{-1} dz = \begin{cases} 0 & \text{if } i \notin X \\ I_i & \text{if } i \in X \end{cases}.
\]

Thus, \(\text{rank } P_{\lambda} = \text{tr} P_{\lambda} = |X| = n\). So the algebraic multiplicity of \(\lambda\) in \(\sigma(K)\) is equal to its number of occurrences on the diagonal.

3.6. Next, we wish to show that, in a number of ways, \(T(M)\) has an abundance of compact operators. In terms of determining the invariant subspace lattice \(\mathcal{N}\), even the rank one operators are sufficient. This is because in the proof of Theorem 2.9, the operator \(T\) constructed may be taken to be rank one. The first result is the converse of Lemma 2.8 for rank one operators.

3.7 Lemma. Let \(x \otimes y^*\) be a rank one operator in \(T(M)\). Then there is an element \(N\) of \(\mathcal{N}\) such that \(x\) belongs to \(N\) and \(y\) belongs to \((N_{-})^\perp\).

Proof. Let \(N\) be the least element of \(\mathcal{N}\) containing \(x\). Let \(N'\) belong to \(\mathcal{N}\) with \(N' < N\), and set \(z = P(N')y\),

\[
0 = P(N')\perp (x \otimes y^*)P(N')z \\
= P(N')\perp x \otimes z^*(x) = \|z\|^2 P(N')\perp x .
\]

Since \(z\) does not belong to \(N'\), \(P(N')\perp x \neq 0\). Thus \(z = P(N')y = 0\). This is valid for all \(N' < N\). Hence \(P(N_{-})y = 0\) as required.

3.8 Proposition. Let \(F\) be a rank-\(n\) operator in \(T(M)\). Then \(F\) is the sum of \(n\) rank one operators in \(T(M)\).
Proof. The proof will proceed by induction on $n$. The cases $n = 0$ and $1$ are immediate. Suppose that $F$ has rank $n$. For $N$ in $\mathcal{H}$, define $f(N)$ to be the dimension of $N \cap \text{Ran}(F)$. Let $k$ be the least, non-zero value attained by $f$. Then $N \cap \text{Ran}(F) = X$ is the same $k$ dimensional space for every $n$ in $f^{-1}(k)$ since $N \cap \text{Ran}(F)$ increases with $N$. Consequently, the infimum $N_0$ of $f^{-1}(k)$ contains $X$. So it is the least element of $\mathcal{H}$ with non-zero intersection with the range of $F$.

Take $x$ to be any unit vector in this intersection, and let $y = F^*x$. For any $N < N_0$ in $\mathcal{H}$, $FP(N)y = P(N)FP(N)y$ belongs to $N \cap \text{Ran} F = \{0\}$. Hence $P(N)y$ belongs to $\ker F = (\text{Ran} F)^\perp$. Hence

$$0 = (P(N)y, F^*x) = (P(N)y, y) = ||P(N)y||^2.$$ 

Thus $y$ belongs to $\bigcap_{N < N_0} N^\perp = (N_0)^\perp$. By Lemma 2.8, $x \otimes y^*$ belongs to $T(\mathcal{H})$.

The rank of $F - x \otimes y^*$ agrees with the rank of its adjoint $F^* - y \otimes x^*$. Since $x$ belongs to $\text{Ran} F = (\ker F^*)^\perp$, this operator annihilates $\ker F^*$. By design, it also annihilates $x$. Thus it has rank at most $n-1$. By the induction hypothesis, $F - x \otimes y^*$ is the sum of $n-1$ rank one operators in $T(\mathcal{H})$, completing the proof. \hfill \blacksquare

The next lemma sets the stage to prove that $T(\mathcal{H}) \cap K$ contains a bounded approximate identity for the compact operators. This will yield a number of nice corollaries.

### 3.9 Lemma. Let $\mathcal{H}$ be a continuous nest. For any unit vector $x$ in $\mathcal{H}$, let $P$ be the orthogonal projection onto $\mathcal{H}'x$. Then $P$ belongs to $\mathcal{H}'$ and there are finite rank operators $R_n = P \Pi_n P$ in $T(\mathcal{H})$ converging to $P$ in the strong* topology, and $\|R_n\| \leq 1$ for all $n$.

Proof. It is clear that the range of $P$ is invariant for $\mathcal{H}'$ and hence $P$ belongs to $\mathcal{H}'$. The map $\phi(N) = ||P(N)x||^2$ is a continuous non-decreasing function of $\mathcal{H}$ onto $[0,1]$ by Theorem 2.13. For $n \leq 1$ and $0 \leq k \leq 2^n$, let $N_{k,n}$ be the least element of $\mathcal{H}$ such that $\phi(N_{k,n}) = k2^{-m}$. Let $E_{k,n} = N_{k,n} \ominus N_{k-1,n}$ be intervals of $\mathcal{H}$. Then

$$x_{k,n} = 2^{-n/2}P(E_{k,n})x$$

is a unit vector in $E_{k,n} \cap \mathcal{H}$. Set

$$R_n = \sum_{k=2}^{2^n} x_{k-1,n} \otimes x_{k,n}^*.$$ 

By Lemma 2.8, $R_n$ belongs to $T(\mathcal{H})$. It is easy to check that $R_n = P \Pi_n P$ and $\|R_n\| = 1$. 
Notice that for \( m > n \)
\[
R_m x_{k,n} = R_m(2^{(n-m)/2} \sum_{j=2^{m-n}(k-1)+1}^{2^{m-n}k} x_{j,m})
= x_{k,n} + 2^{(n-m)/2}(x_{j,(m-n)(k-1),m} - x_{j,(m-n)k,m}).
\]
Hence
\[
\lim_{m \to \infty} R_m y = y
\]
whenever \( y \) belongs to \( \bigcup_{n \geq 1} \text{span} \{ x_{k,n} : 1 \leq k \leq 2^n \} \). But this is dense in \( P\mathcal{N} \) and \( \| R_m \| \leq 1 \). Thus \( R_m \) converges to \( P \) in the strong operator topology.

Finally, if \( y \) belongs to \( P\mathcal{N} \),
\[
\| y \|^2 = \lim_{n \to \infty} (y, R_n y) = (R_n^* y, y).
\]
Since \( \| R_n^* y \| \leq 1 \), it follows that \( \lim R_n^* y = y \). So \( R_n^* \) converges to \( P \) in the strong operator topology as well.

**3.10 Theorem.** Let \( \mathcal{N} \) be a nest. Then there is a net \( F_\alpha \) of finite rank contractions in \( \mathcal{T}(\mathcal{N}) \) such that \( F_\alpha \) converges to the identity in the strong* topology. If \( \mathcal{N} \) is a separable space, the net may be taken to be a sequence \( F_n \).

**Proof.** Let \( P_\alpha \) be the projection into the span of all the atoms of \( \mathcal{N} \). It is trivial to construct an increasing net (or sequence in the separable case) of finite rank projections \( R_\alpha \) in \( \mathcal{N}' \) converging strongly to \( P_\alpha \). The algebra \( P_\alpha \mathcal{T}(\mathcal{N}) P_\alpha \) is a nest algebra \( \mathcal{T}(\mathcal{M}) \) where \( \mathcal{M} \) is a continuous nest. It suffices now to prove the theorem for a continuous nest.

If \( x \) is a unit vector, let \( P_x \) be the orthogonal projection onto \( \mathcal{N}' x \). Let \( \{ P_{x_\alpha} \} \) be a maximal family of such projections which are pairwise orthogonal (Zorn’s lemma). Then \( \sum P_{x_\alpha} = I \) for otherwise any vector \( x \) orthogonal to each \( P_{x_\alpha} \) will extend this set. If \( \mathcal{N} \) is separable, then this is a countable family. For each \( x_\alpha \), one has by Lemma 3.9 a sequence \( R_{n,\alpha} \) of finite rank contractions converging to \( P_{x_\alpha} \) in the strong* topology. Then
\[
R_{n,F} = \sum_{\alpha \in F} R_{n,\alpha}
\]
indexed by \( \mathbb{N} \times \Omega \) where \( \Omega \) is the set of finite subsets of indices is a net of finite rank contractions in \( \mathcal{T}(\mathcal{M}) \) converging strong* to the identity. In the separable case, \( R_{n,n} = \sum_{i=1}^n R_{n,(i)} \) will suffice.

\[\blacksquare\]
3.11 Erdos Density Theorem. The finite rank contractions in $T(\mathcal{N})$ are dense in the unit ball of $T(\mathcal{N})$ in the strong* topology.

**Proof.** Let $T$ be a contraction in $T(\mathcal{N})$, and let $R_\beta$ be the net constructed in Theorem 3.10. Then $TR_\beta$ is a finite rank contractions in $T(\mathcal{N})$, and converges to $T$ in the strong* topology. ■

3.12 Corollary. The norm closure of the finite rank contractions in $T(\mathcal{N})$ is the set of compact contractions in $T(\mathcal{N})$.

**Proof.** By Proposition 1.18, $KR_\beta$ converges to $K$ in norm if $K$ is compact. ■

3.13 Corollary. The span of the rank one operators in $T(\mathcal{N})$ is weak* dense in $T(\mathcal{N})$.

**Proof.** Immediate from Proposition 3.8 and Theorem 3.11. ■

We are now in a position to give a straightforward proof of Lidskii's Theorem about the trace of a trace class operator.

3.14 Corollary. Let $K$ be a trace class operator in $T(\mathcal{N})$. Then $K$ is the limit in the trace norm of finite rank operators in $T(\mathcal{N})$.

**Proof.** By Proposition 1.18, $KR_\beta$ converges to $K$ in the trace norm. ■

3.15 Lidskii's Theorem. Let $K$ be a trace class operator, and let $\{\lambda_n, n \geq 1\}$ be a list of the non zero values in $\sigma(K)$ including multiplicity. Then $\text{tr}(K) = \sum_{n \geq 1} \lambda_n$.

**Proof.** By Corollary 3.2, $K$ is contained in $T(\mathcal{M})$ for some maximal nest $\mathcal{M}$. By Theorem 3.4, the values $\{\lambda_n\}$ occur as the diagonal entries $\{\Phi_{a}(K): A_\alpha \in \mathcal{A}\}$ of $K$ with respect to $\mathcal{M}$, including multiplicity. Define a linear map on the trace class operators in $T(\mathcal{N})$ by

$$\Phi(T) = \sum\Phi_a(T).$$

Let $x_\alpha$ be a unit vector in the atom $A_\alpha$. Then by Theorem 1.3,

$$|\Phi(T)| = |\sum(Tx_\alpha x_\alpha)| \leq \sum |(Tx_\alpha x_\alpha)| \leq \|T\|_1.$$

So $\Phi$ is well defined and has norm at most one.
If $T$ is finite rank, then by standard matrix arguments $tr T$ equals the sum of its eigenvalues. So $tr T = \Phi(T)$. By Corollary 3.14, $K$ is the limit in the trace norm of a sequence $T_n$ of finite rank operators in $T(K)$. Thus

$$tr K = \lim_{n \to \infty} tr T_n = \lim_{n \to \infty} \Phi(T_n) = \Phi(K).$$

Notes and Remarks.

Invariant subspaces for compact operators were obtained independently by von Neumann (unpublished) and Aronszajn and Smith [1]. This was extended to more general operators related to compact operators by Bernstein and Robinson [1], Halmos [1], Arveson-Feldman [1]. Finally, Lomonosov [1] introduced a completely new method to show that if $T$ commutes with a non zero compact operator, then $T$ has a proper invariant subspace. See Radjavi and Rosenthal [2] for a treatment of all these ideas.

Corollary 3.2 and Theorem 3.4 are due to Ringrose [1]. The proof given here is somewhat different than the original, which is done in arbitrary Banach spaces. Theorem 3.8 is in Erdos [3] and is attributed to Ringrose. Theorems 3.10 and 3.11 are due to Erdos. Theorem 3.15 was proved by Lidskii [1] by quite different methods. This proof is due to Erdos [6]. Another proof, due to Power [3], also uses the ideas of nest algebras.

Exercises.

3.1 (Lomonosov, Hilden) Let $K$ be a compact operator, and let $A = \{K\}'$. Prove that $A$ has an invariant subspace as follows: Assume that $A$ has no invariant subspaces.

(i) Show that $\sigma(K) = \{0\}$.

(ii) Let $\|K\| = 1$ and choose $x_0$ with $\|Kx_0\| = 2$. Let $B = \{x : \|x - x_0\| < 1\}$, and $C = KB$. Find open sets $U_1, U_n$ covering $C$ and operator $A_1, \ldots, A_n$ in $A$ such that $A_jy$ belongs to $B$ for all $y$ in $U_j$.

(iii) Find a sequence $j_1, j_2, \ldots$ from $\{1, \ldots, n\}$ such that $A_{j_1}K A_{j_2}K \ldots A_{j_n}Kx_0$ belongs to $B$ for every $p \geq 1$. Show that this contradicts (i).

3.2 Let $V$ be the Volterra operator on $L^2(0,1)$ given by

$$V(x) = \int_x^1 f(t)dt.$$

Prove that $\sigma(V) = \{0\}$ by i) computation of $\|V^n\|$, ii) by an application of Ringrose's Theorem, and iii) by explicitly finding $(V - \lambda I)^{-1}$ for $\lambda \neq 0$. 

3.3 Prove that every quasinilpotent trace class operator is the limit in $C_1$ of a sequence of finite rank nilpotent operators.

3.4 Use Lemma 3.5 to give a simple direct proof that the finite rank operators in $T(N)$ are dense in $T(N) \cap K$.

3.5 (Weyl) Let $T$ be an operator in $C_p$, $1 < p < \infty$. Let $\{\lambda_n\}$ be the eigenvalues of $T$ including multiplicity. Prove that

$$\left( \sum_{n=1}^{\infty} |\lambda_n|^p \right)^{1/p} \leq \|T\|_p.$$  

(Hint: Use Exercise 1.4) Show that equality holds if and only if $T$ is normal.

3.6 (Longstaff) Let $L$ be a lattice of subspaces. For $L$ in $L$, define $L_{-}$ to be the span of $\{M \in L: M \geq L\}$. Show that the rank one operator $x \otimes y^*$ belongs to $Alg L$ if and only if there is an element $L$ in $L$ such that $x$ belongs to $L$ and $y$ belongs to $(L_{-})^\perp$.

3.7 (Lance)

(i) Suppose $x$ and $y$ are vectors in $\mathcal{H}$ and $T$ belongs to $T(N)$ such that $Tx = y$. Show that $\sup_{N \in \mathcal{H}} \|P(N)^{-1} x\| \leq \|T\| < \infty$.

(ii) Let $\mathcal{F}$ be a finite nest $0 = F_0 < F_1 < ... < F_n = \mathcal{H}$ with interval projection $E_i = P(F_i) - P(F_{i-1})$, $1 \leq i \leq n$. Let $x$ and $y$ be vectors and let $x_j = E_j x$ and $y_j = E_j y$. Suppose that $\sum_{j=k}^{n} |y_j|^2 \leq \sum_{j=k}^{n} |x_j|^2$ for $1 \leq k \leq n$. Show that there is a finite rank operator $T$ in $T(\mathcal{F})$ with $\|T\| \leq 1$ and $Tx = y$.

Hint: Use induction on $n$. Suppose $T_1 = E_i^* T_1$ in $T(\mathcal{F})$ has $\|T_1\| \leq 1$ and $T_1 x = E_i^* y$. Show that $\|(I - T_1^* T_1)^{1/2} x\| \geq \|y_1\|$. Hence form $T = T_1 + E_i U(1 - T_1^* T_1)^{1/2}$ where $U$ is a certain rank one partial isometry.

(iii) Let $\mathcal{N}$ be an arbitrary nest. Suppose $x$ and $y$ are vectors such that $\sup_{N \in \mathcal{N}} \|P(N)^{-1} x\| = M < \infty$. Show that there is an operator $T$ in $T(N)$ such that $Tx = y$. 

4. Triangular Truncation

Let $\varepsilon_1, \ldots, \varepsilon_n$ be the standard basis for $\mathbb{R}^n$. The map $\tau_n$ which takes a matrix $A$ to its upper triangular part is a bounded linear map. However, as we shall see, $\|\tau_n\|$ grows like $\log n$. As a result, triangular truncation is not bounded in infinite dimensions. In this section, we will explore this carefully.

4.1 Example. Consider the $n \times n$ matrix

$$
A_n = \begin{bmatrix}
0 & 1 & \frac{1}{2} & \frac{1}{3} & \frac{1}{n-1} \\
-1 & 0 & 1 & \frac{1}{2} & \frac{1}{n-2} \\
-\frac{1}{2} & -1 & 0 \quad 1 \\
-\frac{1}{3} & -\frac{1}{2} & -1 & 0 \\
\frac{1}{n-1} & -\frac{1}{n-2} & -\frac{1}{2} & -1 & 0
\end{bmatrix}
$$

where $a_{ij} = \frac{1}{i-j}$ if $i \neq j$ and $a_{ii} = 0$. Let $T_n = \tau_n(A_n)$ be the upper triangular part. It will be shown that $\|A_n\| \leq \pi$ while $\|T_n\| \geq \frac{4}{5} \log n$. Let $x = (n-1)^{-\frac{1}{n}} \sum_{k=2}^{n} \varepsilon_k$. Then

$$
\|T_n\| \geq \|T_n x\| = (n-1)^{-\frac{1}{n}} \|\sum_{k=1}^{n} b_k \varepsilon_k\|
$$

where $b_k = \sum_{j=1}^{k-1} \frac{1}{j} \geq \log(n+1-k) \geq \log(n/3)$ if $k \leq 2n/3$. Hence

$$
\|T_n\| \geq n^{-\frac{1}{n}} \left(\frac{2n}{3}\right)^{\frac{1}{n}} \log(n/3) = (2/3)^{\frac{1}{n}} \log(n/3)
$$

whence
\[
\lim_{n \to \infty} \frac{\|T_n\|}{\log_2 n} \geq \left(\frac{2}{3}\right)^k \geq 0.8 .
\]

On the other hand, consider the doubly infinite matrix 
\(M = (m_{ij})_{i,j \in \mathbb{Z}}\) where \(m_{ij} = (i-j)^{-1}\) if \(i \neq j\) and \(m_{ii} = 0\) as an operator on \(\ell^2(\mathbb{Z})\). Let \(P_n\) be the projection of \(\ell^2(\mathbb{Z})\) onto the span \(\{e_i, 1 \leq i \leq n\}\). Clearly, \(A_n\) is unitarily equivalent to \(P_n M |P_n\) and thus \(\|A_n\| \leq \|M\|\) for all \(n\). Next, notice that \(M\) is skew adjoint. So \(\|M\|^2 = \|M^2\|\). The operator \(M^2\) has a matrix \((b_{ij})\) where
\[
b_{ij} = \sum_{k=-\infty}^{\infty} m_{ik} m_{kj} = \sum_{k \neq i,j} \frac{1}{(i-k)(j-k)} = -\sum_{n \neq 0, j-i} \frac{1}{n(n-j+i)} .
\]
Thus \(b_{ii} = -\sum_{k \neq 0} \frac{1}{k^2} = -2\sum_{k=1}^{\infty} \frac{1}{k^2} = -\pi^2/3\). And, if \(j-i = r \neq 0\)
\[
b_{ij} = -\sum_{n > r} \frac{1}{n(n-r)} + \sum_{n = r+1}^{\infty} \frac{1}{n(n-r)} - \sum_{n < 0} \frac{1}{n(n-r)}
= -2 \sum_{r+1}^{\infty} \frac{1}{r} + \sum_{r+1}^{\infty} \frac{1}{r+1} + \sum_{n = 1}^{\infty} \frac{1}{n(n-r)}
= -\frac{2}{r} \sum_{n = 1}^{\infty} \frac{1}{n(n-r)} = -\frac{2}{r^2} .
\]
Hence \(M^2 = -\pi^2/3|I - \sum_{2/3}^{\infty} 2/k^2 U^2\) where \(U_{k}\) is the unitary operator shifting \(e_i\) to \(e_{i+k}\). So
\[
\|M^2\| \leq \frac{\pi^2}{3} + \sum_{2/3}^{\infty} \frac{2}{k^2} = 6 \sum_{n=1}^{\infty} \frac{1}{n^2} = \pi^2 .
\]
Hence \(\|A_n\| \leq \|M\| \leq \pi\).

4.2. Let \(\mathcal{F}\) be a finite nest \(\{0\} = N_0 < N_1 < \ldots < N_n = \mathcal{H}\). Set \(P_i = P(N_i)\) and \(\Delta P_i = P_i - P_{i-1}\) for \(1 \leq i \leq n\). For each \(T\) in \(\mathcal{B}(\mathcal{H})\), define
\[
U_{\mathcal{F}}(T) = \sum_{i=1}^{n} P_i T \Delta P_i,
L_{\mathcal{F}}(T) = \sum_{i=1}^{n} P_{i-1} T \Delta P_i,
D_{\mathcal{F}}(T) = \sum_{i=1}^{n} \Delta P_i T \Delta P_i .
\]
These terms are respectively the upper triangular, strictly upper triangular, and diagonal parts of \(T\) with respect to \(\mathcal{F}\). The first two terms can be
thought of as upper and lower sums in a Riemann sum.

Let $\mathcal{N}$ be a nest, and consider the finite subnets $\mathcal{F}$ of $\mathcal{N}$ as a net ordered by inclusion. An operator $T$ has a triangular truncation $\mathcal{U}_\mathcal{N}(T)$ if $\lim_{\mathcal{F}} \mathcal{U}_\mathcal{F}(T)$ exists in norm. Likewise, define strictly upper triangular truncation $\mathcal{L}_\mathcal{N}(T)$ and diagonal $\mathcal{D}_\mathcal{N}(T)$. Similarly define weak versions by replacing norm limits by weak operator limits.

First let us study the diagonal map. Recall from section 2.17 that $\Delta(A)$ is the projection of $A$ onto the atomic part of the diagonal.

4.3 Proposition. If $T = D + K$ where $D$ belongs to $\mathcal{N}'$ and $K$ is compact, then $\mathcal{D}_\mathcal{N}(T)$ converges in norm to $D + \Delta(K)$.

Proof. Since $\mathcal{D}_\mathcal{N}(D) = D$ for every $\mathcal{F}$, it suffices to consider the compact operator $K$. By Lemma 3.5, given $\epsilon > 0$ there is a finite nest $\mathcal{F}_0$ so that $\|E_NKE_N\| < \epsilon$ for every atom of $\mathcal{F}_0$ which is not an atom of $\mathcal{N}$. It follows that $\|\mathcal{D}_\mathcal{N}(K) - \Delta(K)\| < 2\epsilon$ for every $\mathcal{F}$ containing $\mathcal{F}_0$. Thus the proposition is proven. ■

4.4 Proposition. If $\mathcal{N}$ is atomic, then $\mathcal{D}_\mathcal{N}(T)$ converges in the strong operator topology to $\Delta(T)$ for every $T$ in $\mathcal{B}(\mathcal{H})$.

Proof. Let $\{e_i\}$ be an orthonormal basis for $\mathcal{H}$ such that for each $i$, there is an atom $A_i$ containing $e_i$. Consider a vector $x = \sum_{i=1}^{N} a_i e_i$. If $\mathcal{F}$ is any finite subnet of $\mathcal{N}$ so that each $A_i$, $1 \leq i \leq N$, is an atom of $\mathcal{F}$,

$$\mathcal{D}_\mathcal{F}(T)x = \sum_{i=1}^{N} P(A_i)TP(A_i)(a_i e_i) = \Delta(T)x .$$

Since $\mathcal{D}_\mathcal{F}(T)$ is a bounded net (by $\|T\|$) and the algebraic linear span of $\{e_i\}$ is dense in $\mathcal{H}$, $\mathcal{D}_\mathcal{F}(T)y$ converges to $\Delta(T)y$ for every $y$ in $\mathcal{H}$. ■

When $\mathcal{N}$ is not atomic, the net $\mathcal{D}_\mathcal{F}(T)$ does not converge weakly for every operator. A more complete analysis will be given in Theorem 8.6.

Now consider the triangular truncations. The first result is very easy, and left as an exercises.

4.5 Proposition. Let $\mathcal{N}$ be a nest and let $T$ be an element of $\mathcal{T}(\mathcal{N})$. Then $\mathcal{U}_\mathcal{N}(T) = T = \mathcal{U}_\mathcal{N}(T)$ for every finite subnet $\mathcal{F}$ of $\mathcal{N}$. The strictly triangular integral $\mathcal{L}_\mathcal{N}(T)$ exists if and only if $\mathcal{D}_\mathcal{N}(T)$ exists, and in this case $\mathcal{L}_\mathcal{N}(T) = T - \mathcal{D}_\mathcal{N}(T)$.

Thus, if $T$ is compact, $\mathcal{L}_\mathcal{N}(T) = T - \Delta(T)$. □
4.6 Corollary. If \( \mathcal{N} \) is a nest and \( T \) is an element of \( \mathcal{T}(\mathcal{N})^\ast \), then 
\[ L_{\mathcal{N}}(T) = L_T(T) = 0 \]
for every finite subnest \( \mathcal{F} \) of \( \mathcal{N} \). The net \( \mathcal{U}_{\mathcal{N}}(T) = D_T(T) \), so \( \mathcal{U}_{\mathcal{N}}(T) \) exists exactly when \( D_T(T) \) exists. In particular, if \( T \) is compact, \( \mathcal{U}_{\mathcal{N}}(T) = D_T(T) = \Delta(T) \).

Proof. \( \mathcal{T}(\mathcal{N})^\ast = \mathcal{T}(\mathcal{N}^\perp) \) and \( L_{\mathcal{N}}(T) = T - \mathcal{U}_{\mathcal{N}}(T) = 0 \). Also, 
\[ \mathcal{U}_{\mathcal{N}}(T) = T - L_{\mathcal{N}}(T) = D_{\mathcal{N}}(T) = \Delta(T) \]
for every finite subnest of \( \mathcal{N} \). Apply Proposition 4.5.

4.7. If \( \mathcal{U}_{\mathcal{N}}(T) = L_{\mathcal{N}}(T) \), one says that the (upper) triangular integral 
\[ \int \mathcal{N} P(N) T dN \]
exists. The terms \( \mathcal{U}_{\mathcal{N}}(T) \) and \( L_{\mathcal{N}}(T) \) are the upper and lower Riemann sums of this integral.

The two preceding rather trivial results have the following more remarkable consequence.

4.8 Theorem. Let \( \mathcal{N} \) be a nest. Suppose that \( T \) is a compact operator in \( \mathcal{T}(\mathcal{N}) \) such that \( \Delta(T) = 0 \). Then
\[ T = 2 \text{Re} \int \mathcal{N} P(N) T dN = 2i \text{Im} \int \mathcal{N} P(N) T dN . \]

Proof. By Proposition 4.5 and 4.6,
\[ T = \mathcal{U}_{\mathcal{N}}(T) = L_{\mathcal{N}}(T) + \Delta(T) = L_{\mathcal{N}}(T) \]
and
\[ 0 = L_{\mathcal{N}}(T^\ast) = \mathcal{U}_{\mathcal{N}}(T^\ast) - \Delta(T^\ast) = \mathcal{U}_{\mathcal{N}}(T^\ast) \]
Hence
\[ T = \mathcal{U}_{\mathcal{N}}(T \pm T^\ast) = L_{\mathcal{N}}(T \pm T^\ast) . \]
So the integrals of both \( 2 \text{Re} T = T + T^\ast \) and \( 2i \text{Im} T = T - T^\ast \) exist and equal \( T \).

4.9. It is an easy consequence of Example 4.1 that there exist compact self-adjoint operators whose triangular truncation with respect to some nest of order type \( \omega = \mathcal{N} \cup \{ \infty \} \) is unbounded. So Theorem 4.8 is not applicable to all compact operators in \( \mathcal{B}(\mathcal{N}) \). To get a handle on what is going on, it is necessary to consider other ideals of compact operators closed in stronger norms, such as the trace class operators and Hilbert-Schmidt operators. We consider the Hilbert-Schmidt operators first as they are quite easily handled.
4.10 Theorem. Let $\mathcal{N}$ be any nest. Then the triangular truncation operators $\mathcal{U}_\mathcal{N}$, $\mathcal{L}_\mathcal{N}$ and $\mathcal{D}_\mathcal{N}$ are contractive projections of the Hilbert-Schmidt class $C_2$ into itself. Thus they are orthogonal projections.

Proof. Let $\mathcal{F}$ be any finite subnest of $\mathcal{N}$, and let $E_1, \ldots, E_n$ be the orthogonal projections onto the intervals of $\mathcal{F}$. For every operator $T$ in $C_2$,

$$T = \sum_{i=1}^{n} \sum_{j=1}^{n} E_i T E_j.$$

Thus

$$\|T\|^2 = \text{tr}(TT^*) = \text{tr}(\sum_{i,j} E_i E_j T E_i T^* E_j E_i)$$

$$= \text{tr}(\sum_{i,j} \sum_{t} E_i T E_j T^* E_t E_i)$$

$$= \text{tr}(\sum_{i,j} (E_i T E_j)(E_i T E_j)^*) = \sum_{i,j} \|E_i T E_j\|^2.$$

Since $\mathcal{U}_\mathcal{F}(T) = \sum_{i \leq j} E_i T E_j$ and $\mathcal{L}_\mathcal{F}(T) = \sum_{i > j} E_i T E_j$, it follows that

$$\|\mathcal{L}_\mathcal{F}(T)\|^2 \leq \|\mathcal{U}_\mathcal{F}(T)\|^2 \leq \|T\|^2.$$

Also, if $\mathcal{F}_1 \subset \mathcal{F}_2$ are two finite subnets, then another consideration of the terms $E_i T E_j$ yields

$$\|\mathcal{L}_{\mathcal{F}_1}(T)\|^2 \leq \|\mathcal{L}_{\mathcal{F}_2}(T)\|^2 \leq \|\mathcal{U}_{\mathcal{F}_2}(T)\|^2 \leq \|\mathcal{U}_{\mathcal{F}_1}(T)\|^2.$$

and

$$\|\mathcal{L}_{\mathcal{F}_1}(T) - \mathcal{L}_{\mathcal{F}_2}(T)\|^2 = \|\mathcal{L}_{\mathcal{F}_2}(T)\|^2 - \|\mathcal{L}_{\mathcal{F}_1}(T)\|^2$$

and

$$\|\mathcal{U}_{\mathcal{F}_1}(T) - \mathcal{U}_{\mathcal{F}_2}(T)\|^2 = \|\mathcal{U}_{\mathcal{F}_2}(T)\|^2 - \|\mathcal{U}_{\mathcal{F}_1}(T)\|^2.$$

Then $\|\mathcal{L}_\mathcal{F}(T)\|_2$ is monotone increasing and bounded above; $\|\mathcal{U}_\mathcal{F}(T)\|_2$ is monotone decreasing and bounded below. Let $M^2 = \inf_\mathcal{F} \|\mathcal{U}_\mathcal{F}(T)\|_2^2$. For each $\epsilon > 0$, choose $\mathcal{F}_\epsilon$ so that $\|\mathcal{U}_{\mathcal{F}_\epsilon}(T)\|_2^2 \leq M^2 + \epsilon^2$. Then for any finite subnets $\mathcal{F}_1$ containing $\mathcal{F}_\epsilon$,

$$\|\mathcal{U}_{\mathcal{F}_1}(T) - \mathcal{U}_{\mathcal{F}_\epsilon}(T)\|_2^2 \leq M^2 + \epsilon^2 - M^2 = \epsilon^2.$$

Hence $\mathcal{U}_\mathcal{F}(T)$ converges in the $C_2$ norm. Likewise, $\mathcal{L}_\mathcal{F}(T)$ converges. Thus $\mathcal{U}_\mathcal{N}(T)$ and $\mathcal{L}_\mathcal{N}(T)$ are well defined, contractive projections.

The space $C_2$ is a Hilbert space, and every contractive projection on
a Hilbert space is self-adjoint. Finally, $\vartheta \mu = \nu \mu - \nu \mu$ is also a contractive projection. By Proposition 4.3, $D_\mu(T) = \Delta(T)$ for all $T$ in $C_2$.

4.11. In the case of trace class operators, the extreme points of the unit ball are the rank one operators. So it suffices to look at them. Consider, in particular, the rank one operator $1 \otimes 1^*$ in $L^2(0,1)$ and the continuous nest $\mathcal{N} = \{N_t : 0 \leq t \leq 1\}$ of subspaces of functions supported on $[0,t]$. By Theorem 4.8 and the results of the next section, $\mathcal{U}_\nu(1 \otimes 1^*) = V$ is the Volterra operator. By Theorem 5.8, the singular values of $V$ are $\{2/(2n-1)\pi, n \geq 1\}$. Thus $V$ is not trace class, although it belongs to $C_p$ for all $p > 1$. Thus triangular truncation is not bounded in $C_1$. By the easy duality result below, this yields another proof that truncation is not bounded on the compact operators either. However, this example tells us exactly to which ideal the truncations of trace class operators naturally belong.

Let $C_\Omega$ be the normed ideal of compact operators $A$ such that

$$\|A\|_\Omega = \sup_n \frac{\sum_{j=1}^n s_j(A)}{n \sum_{j=1}^n 1/j}$$

is finite. And define $C_\omega$ to be the ideal of all compact operators $A$ such that

$$\|A\|_\omega = \sum_{n=1}^\infty \frac{1}{n} s_n(A)$$

is finite. The ideal $C_\omega$ is known as the Macaev ideal.

The ideal $C_\Omega$ is strictly larger than $C_1$ since it contains all operators whose $\mathcal{s}$-numbers are $O(1/n)$. On the other hand, if $A$ belongs to $C_\Omega$,

$$s_n(A) \leq \frac{1}{n} \sum_{j=1}^n s_j(A) \leq \frac{1}{n} \|A\|_\Omega \sum_{j=1}^n \frac{1}{j}$$

Thus the sequence $s_n(A)$ is $O(\log n)$. This implies that $s_n(A)$ belongs to $\ell^p$ for $p > 1$. So $C_\Omega$ is contained in the intersection of all $C_p$ classes for $p > 1$. Similarly, note that $\{1/n, n \geq 1\}$ belong to $\ell^q$ for all $q > 1$. So if $A$ belongs to $C_p$ then with $\frac{1}{p} + \frac{1}{q} = 1$,
\[ \|A\|_\omega = \sum_{n=1}^{\infty} \frac{1}{n} s_n(A) \leq \|\left(\frac{1}{n}\right)\|_p \|A\|_p < \infty. \]

Thus \( C_\omega \) contains all the \( C_p \) classes for \( p < \infty \).

**4.12 Lemma.** The map \( A \rightarrow \phi_A \) given by \( \phi_A(X) = \text{tr}(AX) \) for \( X \in C_\omega \) is a linear isometry of \( C_\Omega \) onto \( C_\omega \).

**Proof.** Let \( \phi \) be a functional on \( C_\omega \). Proceed as in Theorem 1.13 by considering the sesquilinear form \( \langle x, y \rangle = \phi(x \otimes y^*) \). This satisfies

\[ \|\langle x, y \rangle\| \leq \|\phi\| \|x \otimes y^*\|_\omega = \|\phi\| \|x\| \|y\| \]

Thus there is a bounded linear operator \( A \) with \( \|A\| \leq \|\phi\| \) such that

\[ \phi(x \otimes y^*) = (Ax, y) = \text{tr}(Ax \otimes y^*). \]

Let \( \{e_k, 1 \leq k \leq n\} \) and \( \{f_k, 1 \leq k \leq n\} \) be two orthonormal sets. Then

\[ \left| \sum_{k=1}^{n} \langle A f_k, e_k \rangle \right| = \left| \phi\left( \sum_{k=1}^{n} f_k \otimes e_k^* \right) \right| \]

\[ \leq \|\phi\| \left| \sum_{k=1}^{n} f_k \otimes e_k^* \right|_\omega = \|\phi\| \sum_{k=1}^{n} \frac{1}{k} \]

It follows as in the proof of Theorem 1.13 that \( A \) is compact. Let \( \{e_k\} \) and \( \{f_k\} \) be the orthonormal families such that \( A = \sum_{k=1}^{\infty} s_k(e_k \otimes f_k^*) \). Putting this into the inequality above yields

\[ \sum_{k=1}^{n} s_k(A) \leq \|\phi\| \sum_{k=1}^{n} \frac{1}{k} \]

Then \( \|A\|_\Omega \leq \|\phi\| \). The functionals \( \phi \) and \( \phi_A \) agree on all finite rank operators. These are easily seen to be dense in \( C_\omega \), so \( \phi = \phi_A \).

Conversely, let \( A \) belong to \( C_\Omega \). Let \( \lambda_j \) be positive real numbers such that \( \lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_n \). Let \( \{e_j, 1 \leq j \leq n\} \) and \( \{f_j, 1 \leq j \leq n\} \) be orthonormal sets, and let \( F = \sum_{j=1}^{n} \lambda_j e_j \otimes f_j^* \). Every rank \( n \) operator with \( s \)-numbers \( \lambda_1, \ldots, \lambda_n \) has this form. Set \( \lambda_{n+1} = 0 \), and compute using Lemma 1.7 and summation by parts
\[ |\phi_A(F)| \leq |\text{tr}(A\sum_{j=1}^{n} \lambda_j e_j \otimes f_j)| \]
\[ \leq \sum_{j=1}^{n} \lambda_j |(Ae_j, f_j)| = \sum_{j=1}^{n} (\lambda_j - \lambda_{j+1}) \sum_{k=1}^{j} |(Ae_k, f_k)| \]
\[ \leq \sum_{j=1}^{n} (\lambda_j - \lambda_{j+1}) \sum_{k=1}^{j} 1 \leq \|A\| \sum_{j=1}^{n} (\lambda_j - \lambda_{j+1}) \sum_{k=1}^{j} 1/k \]
\[ = \|A\| \sum_{j=1}^{n} \frac{1}{j} \lambda_j = \|A\| \|\Omega\| F_{\omega}. \]

Since finite rank operators are dense in \( C_\omega \), one obtains \( \|\phi_A\| \leq \|A\| \|\Omega\|. \) Thus equality holds and the theorem is proved. \( \blacksquare \)

**4.13 Lemma** Let \( x \otimes y^* \) be a norm one rank one operator. For every nest \( \mathcal{N} \), \( s_k(U_\mathcal{N}(x \otimes y^*)) \leq \frac{1}{k} \) for all \( k \geq 1 \).

**Proof.** Since \( x \otimes y^* \) is in \( C_2 \), \( U_\mathcal{N}(x \otimes y^*) \) belongs to \( C_2 \) by Theorem 4.10. Consider \( k = 1 \). Then
\[ s_1(U_\mathcal{N}(x \otimes y^*)) = \|U_\mathcal{N}(x \otimes y^*)\| \leq \|x \otimes y^*\|_2 = 1. \]

For \( k \geq 2 \), let \( P_0 = 0 \), \( P_k = I \), and set \( P_j \) to be the projection onto the least element \( N_j \) of \( \mathcal{N} \) such that
\[ \|(P_j - P_{j-1})x \otimes y^*(P_j - P_{j-1})y\| = \|P_j - P_{j-1}\|_2 \|P_j - P_{j-1}\| \geq \frac{1}{k} \]
for \( 1 \leq j \leq k - 1 \). Let \( Q_j = P(N_j \cdot) \). By the minimality of \( P_j \), one has
\[ \|(Q_j - P_{j-1})x\| \|Q_j - P_{j-1}\| y\| \leq \frac{1}{k} \]
for \( 1 \leq j \leq k - 1 \). And by the Cauchy-Schwartz inequality,
\[ 1 = \|x\| \|y\| \geq \sum_{j=1}^{k} \|(P_j - P_{j-1})x\| \|(P_j - P_{j-1})y\| \geq 1 - \frac{1}{k} + \|P_{k-1}^\perp x\| \|P_{k-1}^\perp y\|. \]

Thus \( \|P_{k-1}^\perp x\| \|P_{k-1}^\perp y\| \leq \frac{1}{k} \). Write \( E_j = Q_j - P_{j-1} \) for \( 1 \leq j \leq k - 1 \), and \( E_k = P_{k-1}^\perp \).
By Lemma 1.4, if $K$ has rank at most $k-1$, then
\[ s_k(\mathcal{U}(x \otimes y^*)) \leq \|\mathcal{U}(x \otimes y^*) - K\| . \]

Define $K = \sum_{j=1}^{k-1} (P_j - P_{j-1})x \otimes Q_j^*y^*$. This has rank at most $k-1$. Let $\mathcal{F}$ be the finite subnest $\{0, N_{1-}, N_1, ..., N_{k-1-}, N_{k-1}, \mathcal{N}\}$. One can see that
\[ \mathcal{U}(x \otimes y^*) = \sum_{j=1}^{n} E_j x \otimes P_j^*y^* + (P_j - Q_j)x \otimes Q_j^*y^* \]
\[ = K + \sum_{j=1}^{n} E_j x \otimes E_j y^* . \]

Therefore,
\[ \mathcal{U}(x \otimes y^*) - K = \mathcal{U}(\mathcal{U}(x \otimes y^*) - K) = \sum_{j=1}^{n} \mathcal{U}(E_j x \otimes E_j y^*) . \]

This is a sum of orthogonal terms. So by the $k = 1$ case,
\[ s_k(\mathcal{U}(x \otimes y^*)) \leq \max_{1 \leq j \leq n} \|\mathcal{U}(E_j x \otimes E_j y^*)\| \]
\[ \leq \max_{1 \leq j \leq n} \|E_j x\| \|E_j y\| \leq \frac{1}{k} . \]

**4.14 Theorem.** For every nest $\mathcal{N}$, the operator $\mathcal{U}$ carries $C_1$ into $C_0$ and $\|\mathcal{U}(T)\|_0 \leq \|T\|_1$.

**Proof.** By Lemma 4.13, this holds for rank one operators. In general, $T = \sum_{k \geq 1} s_k e_k \otimes f_k^*$ where $s_k = s_k(T)$ and $\{e_k\}$, $\{f_k\}$ are orthonormal sequences. Thus
\[ \|\mathcal{U}(T)\|_0 \leq \sum_{k \geq 1} s_k \|\mathcal{U}(e_k \otimes f_k^*)\|_0 \leq \sum_{k \geq 1} s_k = \|T\|_1 . \]

Now, we employ duality methods to show that $\mathcal{U}$ is bounded from the Macaev ideal $C_0$ into $K$.

**4.15 Lemma.** Let $A$ belong to $B(\mathcal{L})$, and let $T$ be trace class. For every finite nest $\mathcal{F}$, $tr(\mathcal{U}(A)T) = tr(A\mathcal{U}(T))$.

**Proof.** Let $\mathcal{F}$ be given by projections $0 = P_0 < P_1 < ... < P_n = I$.
\[ tr(\mathcal{U}(A)T^*) = \sum_{j=1}^{n} tr(P_j A (P_j - P_{j-1}) T^*) = \sum_{j=1}^{n} tr(A (P_j T (P_j - P_{j-1})^*) = tr(A \mathcal{U}(T)^*) \]

4.16 **Theorem.** Let \( \mathcal{N} \) be a nest. For every \( A \) in \( C_\omega \), \( \mathcal{U}_\mathcal{N}(A) = \lim_\mathcal{F} \mathcal{U}_\mathcal{F}(A) \) exists, and \( \| \mathcal{U}_\mathcal{N}(A) \| \leq \| A \|_\omega \). Thus \( \mathcal{U}_\mathcal{N} \) is a contractive map from \( C_\omega \) into \( \mathcal{K} \).

**Proof.** Let \( \mathcal{F} \) be a finite subnest of \( \mathcal{N} \). Then \( \mathcal{U}_\mathcal{F}(A) \) is compact, and there are unit vectors \( x \) and \( y \) such that
\[
\| \mathcal{U}_\mathcal{F}(A) \| = \langle \mathcal{U}_\mathcal{F}(A)x, y \rangle = tr(\mathcal{U}_\mathcal{F}(A)(y \otimes x)^*) = tr(A(y \otimes x)^*) \leq \| A \|_\omega \| \mathcal{U}_\mathcal{F}(y \otimes x)^* \|_\Omega \leq \| A \|_\omega
\]
by Theorem 4.14 and Lemma 4.15.

Let \( \epsilon > 0 \) be given. Since the finite rank operators are dense in \( C_\omega \), choose a finite rank operator \( X \) so that \( \| A - X \|_\omega < \epsilon \). By Theorem 4.10, there is a finite subnest \( \mathcal{F}_\epsilon \) of \( \mathcal{N} \) so that if \( \mathcal{F}_1 \) and \( \mathcal{F}_2 \) are finite subests containing \( \mathcal{F}_\epsilon \), then \( \| \mathcal{U}_{\mathcal{F}_1}(X) - \mathcal{U}_{\mathcal{F}_2}(X) \|_2 < \epsilon \). Thus
\[
\| \mathcal{U}_{\mathcal{F}_1}(A) - \mathcal{U}_{\mathcal{F}_2}(A) \| \leq \| \mathcal{U}_{\mathcal{F}_1}(A - X) \| + \| \mathcal{U}_{\mathcal{F}_1}(X) - \mathcal{U}_{\mathcal{F}_2}(X) \| + \| \mathcal{U}_{\mathcal{F}_2}(X - A) \| \leq \| A - X \|_\omega + \| \mathcal{U}_{\mathcal{F}_1}(X) - \mathcal{U}_{\mathcal{F}_2}(X) \|_2 + \| A - X \|_\omega \leq 3\epsilon.
\]
Hence \( \mathcal{U}_\mathcal{F}(A) \) is norm convergent. Thus \( \mathcal{U}_\mathcal{N}(A) \) is compact, and
\[
\| \mathcal{U}_\mathcal{N}(A) \| = \lim_\mathcal{F} \| \mathcal{U}_\mathcal{F}(A) \| \leq \| A \|_\omega.
\]

4.17 **Corollary.** Let \( \mathcal{N} \) be a nest. For every \( A \) in \( C_\omega \), \( L_\mathcal{N}(A) = \lim_\mathcal{F} L_\mathcal{F}(A) \) exists, and \( \| L_\mathcal{N}(A) \| \leq \| A \|_\omega \). Thus \( \int_\mathcal{N} \rho(N)A dN \) exists if and only if \( \Delta(A) = 0 \).

**Proof.** By Proposition 4.3, \( D_\mathcal{N}(A) = \Delta(A) = \lim_\mathcal{F} D_\mathcal{F}(A) \) in norm. Thus \( L_\mathcal{N}(A) = \mathcal{U}_\mathcal{N}(A) - D_\mathcal{N}(A) \) exists, and is bounded. To obtain the sharp norm estimate, one must modify Lemma 4.13 for \( L_\mathcal{F} \).

Theorems 4.14 and 4.16 are evidence that \( C_\omega \) is the proper ideal for triangular truncation. Theorem 4.19 below is the converse, which shows that no larger idea will do.
4.18 Lemma. Let $D$ be a diagonal, self-adjoint operator with eigenvalues $\{\lambda_n, n \in \mathbb{Z}\}$ such that $\lambda_n/(2n-1) \geq 0$ for all $n$ and $\sum_{n=-\infty}^{\infty} \frac{\lambda_n}{2n-1} = \infty$. Then there is a continuous nest $\mathcal{N}$ so that the net $U_x(D)$ does not converge in the weak operator topology.

**Proof.** Let the eigenvector for $\lambda_n$ be $e_n$. After a unitary equivalence, we may suppose that $\mathcal{N} = L^2(0,1)$ and $e_n = e_n(t) = e^{(2n-1)t}$. Let $\mathcal{N}$ be the continuous nest $\{N_t, 0 \leq t \leq 1\}$ where $N_t$ is the space of functions supported on $[0,t]$. Let $\mathcal{N}_m$ denote the subnest $\{N_{k/m}, 0 \leq k \leq m\}$. It will be shown that

$$u_m = (U_{\mathcal{N}_m}(D)1,1)$$

diverges. Let $P_t = P(N_t)$,

$$u_m = \left( \sum_{k=1}^{m} P_{k/m}D(P_{k/m} - P_{k-1/m})1,1 \right)$$

$$= \sum_{k=1}^{m} \sum_{n=-\infty}^{\infty} \lambda_n f_{k-1/m}^{k/m} e_n(t)dt \int_{0}^{k/m} e_n(t)dt$$

$$= \sum_{k=1}^{m} \sum_{n=-\infty}^{\infty} \lambda_n \frac{(2n-1)^{2/\pi}}{2} (e_n(-k/m) - e_n((1-k)/m)(e_n(k/m) - 1)$$

$$= \sum_{n=-\infty}^{\infty} \lambda_n \frac{(2n-1)^{2/\pi}}{2} \sum_{k=1}^{m} 1 - e_n(1/m) + e_n((1-k)/m) - e_n(-k/m)$$

$$= \sum_{n=-\infty}^{\infty} \lambda_n \frac{(2n-1)^{2/\pi}}{2} (m - me_n(1/m) - 2)$$

Thus

$$\text{Im} \ u_m = -\frac{m}{\pi^2} \sum_{n=-\infty}^{\infty} \frac{\lambda_n}{(2n-1)^2} \sin \frac{(2n-1)\pi}{m}.$$ 

For convenience, take $m = 4p$. Then since $\sin \theta \geq 2\theta/\pi$ for $0 \leq \theta \leq \pi/2$,

$$\frac{4p}{\pi^2} \sum_{n=-p+1}^{p} \frac{\lambda_n}{(2n-1)^2} \sin \frac{(2n-1)\pi}{4p} \geq \frac{4p}{\pi^2} \sum_{n=-p+1}^{p} \frac{\lambda_n}{(2n-1)^2} \frac{(2n-1)}{2p}$$

$$= \frac{2}{\pi^2} \sum_{n=-p+1}^{p} \frac{\lambda_n}{2n-1}.$$ 

And
\[ \frac{4p}{\pi^2} \sum_{n \leq p} + \sum_{n = p+1}^{\infty} \frac{\lambda_n}{(2n-1)^2} \sin \left( \frac{2n-1-\pi}{4p} \right) \leq \frac{4p}{\pi^2} \| D \| \sum_{n = p+1}^{\infty} \frac{1}{(2n-1)^2} \leq \frac{8\| D \|}{\pi^2} < \| D \| . \]

Thus

\[ \text{Im } u_{4p} \leq \frac{-2}{\pi^2} \sum_{n = p+1}^{\infty} \frac{\lambda_n}{2n-1} + \| D \| . \]

This tends to \(-\infty\) by hypothesis. Hence \(u_m\) diverges.

4.19 Theorem. Let \(A\) be an operator such that for every continuous nest \(\mathcal{N}\), \(\mathcal{U}_\mathcal{N}(A) = w-\lim \mathcal{U}_\mathcal{F}(A)\) exists in the weak operator topology. Then \(A\) belongs to \(CI+C_w\).

Proof. Say that \(A\) is universally truncatable if it satisfies the hypothesis of this theorem. If \(A\) has this property, so does \(A^*\). For if \(\mathcal{F}\) is a finite nest, \(\mathcal{U}_\mathcal{F}(A^*) = \mathcal{U}_{\mathcal{F}^*)(A)^*}\) where \(\mathcal{F}^*) is the nest of complements of \(\mathcal{F}\). Thus if \(\mathcal{F}\) are the subnests of \(\mathcal{N}\),

\[ w-\lim \mathcal{U}_\mathcal{F}(A^*) = w-\lim \mathcal{U}_{\mathcal{F}^*}(A)^* = \mathcal{U}_{\mathcal{N}^*}(A)^* = \mathcal{U}_\mathcal{N}(A^*) \]

exists for every continuous nest \(\mathcal{N}\). So it suffices to consider the self-adjoint case.

If \(A\) is universally truncatable, so is \(A+\lambda I+K\) for every scalar \(\lambda\) and every \(K\) in \(C_2\). So choose \(\lambda\) so that \(0\) is in the essential spectrum. Then use the Weyl-von Neumann Theorem to perturb \(A\) by a \(C_2\) operator \(K\) so that it is diagonalizable. A further \(C_2\) perturbation will arrange that infinitely many eigenvalues are positive and infinitely many are negative. If this resulting operator \(D\) is not in \(C_w\), the eigenvalues can be ordered so as to satisfy Lemma 4.18. This is a contradiction. So \(D\) is in \(C_w\), and hence \(A\) belongs to \(CI+C_w\).

Notes and Remarks.

Example 4.1 is based on the fact that the truncation operation sending a Fourier series of a bounded function to its analytic part is unbounded. Indeed, it is a classical theorem of M. Riesz that this map is bounded on \(L^p\) for \(1 < p < \infty\) but not on \(L^1\) or \(L^\infty\). This analogue goes over to the \(C_p\) classes (Dunford and Schwartz [1] XI.10). Our example specifically corresponds to the imaginary part of \(2\log(1-z)\) which \(2\text{Arg}(1-z)\). This is bounded by \(\pi\) which explains \(\| M \| = \pi\), since \(M\) is unitarily equivalent via the Fourier transform of \(L^2\) onto \(\ell^2\) to multiplication by \(2\text{Arg}(1-z)\). The triangular truncation "is" multiplication by the unbounded function \(\log(1-z)\), and thus is not a bounded operator. The proof that \(\| M \| = \pi\) given here is due to Choi [1].
The book of Gohberg and Krein [2] contains a detailed study of triangular truncation and triangular integrals. The bulk of this chapter - Theorems 4.14, 4.16 and 4.19 are due to Macaev, Gohberg and Krein. The proof of Lemmas 4.13 through 4.16 are based on a much simpler argument due to Erdos [8]. The result of Lemma 4.13 is not sharp. The best bound for $s_k$ is $1/2k-1$, and this is sharp.

Exercises.

4.1 Let $T$ be a quasinilpotent operator such that $ImT$ is trace class. Prove that $T$ belongs to $C_0$.

4.2 Prove that if $\mathcal{F}$ is a finite nest with $n$ atoms, then the norm of $U_{\mathcal{F}}$ on $B(\mathcal{H})$ is at most $\sum_{k=1}^{n} \frac{1}{k}$.

4.3 Modify Lemma 4.13 to prove that $\|L_{\mathcal{H}}(A)\| \leq \|A\|_{\omega}$ for every $A$ in $C_{\omega}$.

4.4* Is there a more elementary way to show that the norm of triangular truncation on $M_n$ increases like $log n$? For example, can one inductively construct $A_n$ in $M_{2^n}$ with $\|A_n\| \leq 1$ but $\|T(A_n)\| \geq Cn$?

4.5 Let $\mathcal{H}$ be the Volterra nest on $L^2(0,1)$.

(i) Show that to every operator $K$ in $C_2$, one can associate a unique element $k(x,y)$ in $L^2((0,1)^2)$ such that

$$Kf(x) = \int k(x,y)f(y)dy.$$ 

(ii) Show that the map $U$ taking $K$ to $k$ is unitary.

(iii) Show that $U_{\mathcal{H}}(K) = U^*PU(K)$ where $P$ is the projection $L^2((0,1)^2)$ onto $\{f: suppf \subseteq \{(x,y): x \leq y\}$. 
5. The Volterra Operator

Consider the classical Volterra operator defined in $L^2(0,1)$ given by

$$Vf(t) = \int_0^1 f(x)dx$$

The purpose of this section is to characterize $V$ up to unitary equivalence in a rather striking way. It is clear that each element of $N_1$ of the natural continuous nest $\mathcal{N}$ on $L^2(0,1)$ given in Example 2.4 is invariant for $V$. So $V$ belongs to $T(\mathcal{N})$. Since $\mathcal{N}$ is a continuous nest, the diagonal map $\Delta$ is the zero map. Hence by Ringrose's Theorem 3.4, $V$ is quasinilpotent. Next, compute

$$(V^*f,g) = (f,V^*g) = \int_0^1 f(t)\int_0^1 g(x)dxdt = \int_0^1 (f(\int_0^x f(t)dt)g(x))dx$$

So

$$V^*f(x) = \int_0^x f(t)dt$$

In particular,

$$V^*x^n = \frac{x^{n+1}}{n+1}.$$  

Since the polynomials are dense in $L^2(0,1)$, it follows that $1$ is a cyclic vector for $V^*$.

5.1 Lemma. $V$ is irreducible. (i.e. $\{V, V^*\}' = \mathbb{C}I$).

Proof. $2ReV = V^* + V$ is the rank one operator $1 \otimes 1^*$ since

$$(V + V^*)f(t) = \int_0^1 f(t)dt = <f,1>_1(t).$$

If $P$ is a projection commuting with $V$, then $P$ commutes with $V + V^*$ and hence $\mathbb{C}I$ is invariant. Thus $P1 = 1$ or $0$. If $P1 = 1$, consider $P^\perp$ instead. So without loss of generality, $P1 = 0$. Then

$$\frac{P}{n!}x^n = PV^n1 = V^nP1 = 0.$$  

So $P = 0$.

An operator $T$ is completely non-normal if it has no non-zero reducing subspace $M$ such that $T|_M$ is normal. The Volterra operator is completely non-normal by Lemma 5.1.
5.2 Lemma. Let $Q$ be a completely non-normal quasinilpotent operator such that $Q+Q^*$ is a rank one projection $e \otimes e^*$. Then $Q$ is compact and irreducible and $e$ is a cyclic vector for both $Q$ and $Q^*$.

Proof. Since $Q-Q^* = 2Q-(Q+Q^*)$, the essential spectrum $\sigma_0(Q-Q^*) = \{0\}$. But $Q-Q^*$ is normal, thus $\|Q-Q^*\|_e = \text{spr}_e(Q-Q^*) = 0$. That is, $Q-Q^*$ is compact. Hence $Q = \frac{1}{2}(Q+Q^*) + \frac{1}{2}(Q-Q^*)$ is compact. For any vector $x$,

$$
Q^*x = (Q+Q^*)x - Qx = (x,e)x - Qx.
$$

Thus, the smallest invariant subspace $M$ for $Q$ containing $e$ is also the smallest invariant subspace for $Q^*$. Hence $M$ reduces $Q$. Since $Q+Q^*|M^\perp = 0$, $Q|M^\perp$ is skew-adjoint. But $Q$ is completely non-normal. Thus $M = vA$, and $e$ is cyclic for $Q$ and $Q^*$. The remainder of the proof mimics Lemma 5.1. Briefly, any projection $P$ computing with $Q$ must satisfy $Pe = e$ or $0$. Since $e$ is cyclic, one has $PQ^*e = Q^*Pe = 0$ implying $P = 0$ in the second case. In the first case $P = I$. So $Q$ is irreducible.  

5.3 Lemma. Let $Q$ be a compact, quasinilpotent, completely non-normal operator such that $Q+Q^*$ is a rank one projection $e \otimes e^*$. Let $\mathcal{M}$ be a maximal nest of invariant subspaces for $Q$. Then $\mathcal{M}$ is a continuous nest parametrized by the strictly increasing continuous function

$$
t(M) = (P(M)e,e) .
$$

Proof. Suppose that $M_1 \subseteq M_2$ are two subspaces in $\mathcal{M}$ such that $t(M_1) = t(M_2)$. Let $A = M_2 \ominus M_1$, and $E = P(A)$. By hypothesis, $(Ee,e) = 0$, whence $Ee = 0$. So,

$$
(Q+Q^*)E = 0 = E(Q+Q^*) \quad (5.3.1)
$$

Decompose $\mathcal{H}$ as $M_1 \oplus A \oplus M_2^\perp$. Then $Q$ has a $3 \times 3$ upper triangular matrix $(Q_{ij})$. Plugging this into (5.3.1) yields $Q_{12} = 0 = Q_{23}$. So $EQ = QE$. By Lemma 5.2, $E$ is scalar and hence $E = 0$. So $M_1 = M_2$. This shows that $t$ is a strictly increasing function.

Suppose that $\mathcal{M}$ has an atom $A = M^+ \ominus M$. Since $\sigma(Q) = \{0\}$, Ringrose’s Theorem 3.4 implies that $P(A)QP(A) = 0$. By adding this to its adjoint, one obtains

$$
0 = P(A)EP(A) = P(A)e \otimes (P(A)e)^* .
$$
Thus \( P(A)e = 0 \), and
\[
t(M^a) = (P(A)e,e) + (P(M)e,e) = t(M)
\]
This contradicts the first paragraph. Hence \( \mathcal{M} \) is continuous. \( \blacksquare \)

5.4 Theorem. Every quasinilpotent, completely non-normal operator \( Q \) such that \( Q + Q^* \) is a rank one projection is unitarily equivalent to the Volterra operator \( V \).

5.5 Theorem. \( \text{Lat}(V) = \mathcal{H} = \{ N_t, 0 \leq t \leq 1 \} \).

Proof. These two theorems will be proved together.

Let \( \mathcal{M} \) be a maximal nest of invariant subspaces for \( Q \). Let \( e \otimes e^* = Q + Q^* \), and let \( t(M) \) be the function of Lemma 5.3. Index \( \mathcal{M} \) as \( \{ M_t : 0 \leq t \leq 1 \} \) such that \( t(M_t) = t \). First, we claim that \( e \) is a cyclic vector for \( \mathcal{M}^a \). To see this, let \( P \) be the orthogonal projection onto the closed linear span of \( \{ M_t e : 0 \leq t \leq 1 \} \). This is invariant for \( \mathcal{M} \), so \( P \) belongs to \( \mathcal{M}' \). The operator \( T = Q - PQP \) belongs to \( T(\mathcal{M}) \). Furthermore, since \( Pe = e \),
\[
T + T^* = Q + Q^* - P(Q + Q^*)P = 0
\]
Hence \( T \) is a compact normal operator in \( T(\mathcal{M}) \). By Theorem 3.4, \( \sigma(T) = \{ 0 \} \) and hence \( T = 0 \). It follows that \( P \) commutes with \( Q \). By Lemma 5.2, \( P = I \) so \( e \) is cyclic for \( \mathcal{M}^a \).

Define a linear map \( U \) of \( L^2([0,1]) \) into \( \mathcal{H} \) as follows. Let \( f \) be a step function; that is, there are \( 0 = t_0 < t_1 < \ldots < t_n = 1 \), \( x_i \) are the characteristic functions of \( [t_{i-1}, t_i] \), and \( f \) has the form \( \sum_{i=1}^{n} a_i x_i \). Define \( E_i = P(M_{t_i}) - P(M_{t_{i-1}}) \), and set
\[
Uf = \sum_{i=1}^{n} a_i E_i e
\]
It is clear that this is well defined since any refinement of the partition \( \{ t_i \} \) will yield the same sum. Thus \( U \) is a linear operator on the dense subspace of step functions. Let \( f \) and \( g \) be two step functions, written as \( f = \sum_{i=1}^{n} a_i x_i \) and \( g = \sum_{i=1}^{n} b_i x_i \) with respect to a common subdivision \( \{ t_i \} \) of \( [0,1] \). Then
\[(Uf, Ug) = \left(\sum_{i=1}^{n} a_i E_i e, \sum_{j=1}^{n} b_j E_j e\right) = \sum_{i=1}^{n} a_i b_i(E_i e, e)\]
\[= \sum_{i=1}^{n} a_i b_i(t_i - t_{i-1}) = \sum_{i=1}^{n} a_i b_i(x_i, x_i)\]
\[= \left(\sum_{i=1}^{n} a_i x_i, \sum_{j=1}^{n} b_j x_j\right) = (f, g) .\]

Thus \(U\) is isometric, and therefore extends to an isometry which we also denote by \(U\), of \(L^2(0,1)\) into \(\mathcal{H}\). The range of \(U\) is spanned by \(\{M_t e : 0 \leq t \leq 1\}\) which is dense in \(\mathcal{H}\) by the previous paragraph. Thus \(U\) is unitary.

By Theorem 4.8, one has
\[V = \int_{\mathcal{H}} P(N)(V + V^*)dN = \lim_{\gamma} U_f(1 \otimes 1^*)\]
and
\[Q = \int_{\mathcal{M}} P(M)(Q + Q^*)dM = \lim_{\gamma} U_g(e \otimes e^*) .\]

Let \(f = N_t 1\), and consider a partition \(0 = t_0 < ... < t_{i_0} = t < ... < t_n = 1\). Let \(\mathcal{F} = \{N_{t_i}\}\) and \(\mathcal{G} = \{M_{t_i}\}\) be the corresponding finite subnets of \(\mathcal{H}\) and \(\mathcal{M}\). Set \(P_i = P(N_{t_i})\) and \(R_i = P(M_{t_i})\). Then
\[U_f(1 \otimes 1^*)f = \sum_{i=1}^{n} \left(P_i P(N_{t_i})1, (P_i - P_{i-1})1\right) P_i 1 = \sum_{i=1}^{i_0} (t_i - t_{i-1}) P_i 1\]
and
\[U_g(e \otimes e^*)U_f = \sum_{i=1}^{n} \left(R_i P(M_{t_i})e, (R_i - R_{t_{i-1}})e\right) R_i e = \sum_{i=1}^{i_0} (t_i - t_{i-1}) R_i e .\]

Hence \(UU_f(1 \otimes 1^*)f = U_g(e \otimes e^*)Uf\). Taking this to the limit yields \(UVf = QUf\) for each \(f = N_t 1\). As these vectors span \(L^2(0,1)\), it follows that \(UV = QU\), whence \(Q = UVU^*\).

It is significant that this unitary \(U\) has the further property that \(UN_t = M_t\) for all \(0 \leq t \leq 1\). Suppose that \(V\) has an invariant subspace \(L\). Let \(L\) be a maximal nest of invariant subspaces of \(V\) containing \(L\). By the results above, one obtains a unitary \(U\) such that \(UV = VU\) and \(U^*L = N_t\) for some \(0 \leq t \leq 1\). By Lemma 5.1, \(U\) is scalar and thus \(L\) belongs to \(\mathcal{N}\). So \(\mathcal{N}\) consists of all the invariant subspaces of \(V\).

5.6 Remark. The use of Ringrose’s Theorem in the first paragraph of the proof is not really necessary. The operator \(iT\) is a compact, self-adjoint operator in \(\mathcal{T}(\mathcal{M})\), and hence belongs to \(\mathcal{M}'\). Thus \(\mathcal{M}'\) contains every spectral projection of \((iT)\) which are all finite dimensional unless \(T = 0\). But since \(\mathcal{M}\) is continuous, \(\mathcal{M}'\) contains no finite rank operators.
5.7 Corollary. \( V \) is unitarily equivalent to \( V^* \).

Proof. This follows as a Corollary or by direct computation using \( Uf(x) = f(1-x) \).

It is not trivial to compute \( \|V\| \). In the next theorem, we compute all the \( s \)-numbers of \( V \).

5.8 Theorem. The eigenvalues of \((V^*V)^s\) are \( \frac{2}{(2n-1)\pi} \) for \( n \geq 1 \). In particular, \( \|V\| = 2/\pi \).

Proof. The spectrum of \( V^*V \) consists entirely of eigenvalues since this is a compact self-adjoint operator. So consider this equation for \( \lambda \neq 0 \):

\[
\lambda f(x) = V^*Vf(x) = \int_0^\pi (\int_0^1 f(s)f(\theta)ds)dt .
\]

The right hand side is differentiable by the Fundamental Theorem of Calculus. Repeated application shows that \( f \) is \( C^\infty \). Moreover,

\[
\lambda f'(x) = \int_0^1 f(s)ds
\]

and

\[
\lambda f''(x) = -f(x) .
\]

The boundary conditions are \( f(0) = 0 \) and \( f'(1) = 0 \). This has solutions

\[
f_n(x) = \sin(\frac{2n-1}{2}\pi x), \quad \lambda_n = \left(\frac{2}{(2n-1)\pi}\right)^2 \text{ for } n \geq 1 .
\]

It is well known that this forms a complete orthogonal set for \( L^2(0,1) \). Consequently, \( \sigma((V^*V)^s) \) consists of \( \left\{\frac{2}{(2n-1)\pi} : n \geq 1\right\} \).

5.9. Next, we consider certain algebras related to \( V \). It will be more convenient to work with \( V^* \). It is an easy exercise to show that

\[
V^m f(x) = \int_0^\pi \frac{1}{(n-1)!} (x-t)^{n-1} f(t)dt .
\]

Given a polynomial \( p(x) = \sum_{j=1}^n a_j x^j \), set \( \tilde{p}(x) = \sum_{j=1}^n \frac{a_j}{(j-1)!} x^{j-1} \). Then

\[
p(V^*) f(x) = \int_0^\pi \tilde{p}(x-t)f(t)dt .
\]

Hence
\[ \| p(V^*) f \|^2 = \int_0^1 \int_0^t \tilde{p}(x-t) f(t) \, dt \, dx \leq \int_0^1 \| \tilde{p} \|_2^2 \| f \|^2 \, dt = \| \tilde{p} \|_2^2 \| f \|_2^2 . \]

So \( \| p(V^*) \| \leq \| \tilde{p} \|_2 \).

### 5.10 Theorem

Every operator in \( \{ V^* \}' \) is a limit of a sequence of polynomials in \( V^* \) in the strong operator topology. So \( \{ V^* \}' \) coincides with the weak and weak* closed algebras generated by \( V^* \).

**Proof.** Let \( T \) be an operator commuting with \( V^* \). First suppose that \( T1 = \tilde{p} \) is a polynomial, and let \( p \) be the polynomial related to \( \tilde{p} \) as above.

Then

\[
T(\frac{x^n}{n!}) = TV^n = V^n T = V^n \tilde{p} = V^n p(V^n) 1 = p(V^n)(\frac{x^n}{n!}) .
\]

Since polynomials are dense in \( L^2(0,1) \), \( T = p(V^n) \).

In general, let \( T1 = f \) and choose a polynomial \( \tilde{p}_n \) so that \( \| f - \tilde{p}_n \|_2 \leq 1/n \). Let \( p_n \) be such that \( p_n(V^n)1 = \tilde{p}_n \). Then

\[
\| (T-p_n(V^n))(\frac{x^n}{n!}) \| = \| (T-p_n(V^n))V^n 1 \| = \| V^n (T-p_n(V^n))1 \|
\]

\[
= \| V^n (f-\tilde{p}_n) \| \leq \| V^n \|/n .
\]

It follows that \( p_n(V^n)h \) converges to \( Th \) whenever \( h \) is a polynomial. Since \( \| p_n(V^n) \| \leq \| \tilde{p}_n \|_2 \leq \| f \|_2 + 1/n \) is uniformly bounded, \( p_n(V^n) \) converges to \( T \) in the strong operator topology.

Thus the unit ball of the algebra generated by \( V^* \) is strongly dense in the unit ball of \( \{ V^* \}' \). A fortiori, it is dense in the weak operator topology. As this topology coincides with the weak* topology on bounded sets, it is also weak* dense.

### 5.11 Corollary

\( \{ V^* \}' \) coincides with the weak* closed algebra \( \hat{A}(V) \) generated by \( V \).

**Proof.** Immediate from Corollary 5.7 and Theorem 5.10.

The algebra \( \hat{A}(\mathcal{H}) \) is not singly generated as a (weak* closed) algebra since it is not abelian. It is, however, doubly generated. Let \( M_z \) be the
operator of multiplication by \( z \) on \( L^2(0,1) \). It follows from the double commutant theorem that
\[
\{M_z\}' = \{M_z\}'' = \{M_f : f \in L^\infty(0,1)\}.
\]

5.12 Theorem. The unit ball of the algebra generated by \( \{V, M_z\} \) is strongly dense in the unit ball of \( \mathcal{T}(\mathcal{H}) \). In particular, \( \mathcal{T}(\mathcal{H}) \) is generated by \( \{V, M_z\} \) as a weak\(^*\) closed algebra.

Proof. It is easy to see that the polynomials \( p(M_z) = M_p \) with \( \|p\|_\infty \leq 1 \) are strong\(^*\) dense in the unit ball of \( \{M_z\}' = \mathcal{H}' \). Let \( N \) be an element of \( \mathcal{H} \), and let \( f \) and \( g \) be any bounded functions in \( L^2(0,1) \) such that \( P(N)f = f \) and \( P(N)^\perp g = g \). Then
\[
M_fVM_g = M_fP(N)VP(N)^\perp M_g \\
= M_fP(N)(V + V^*)P(N)^\perp M_g \\
= M_f(1 \otimes 1^*)M_g = f \otimes g^*.
\]

Let \( p_n \) and \( q_n \) be sequences of polynomials so that \( M_{p_n} \) and \( M_{q_n} \) converge strongly to \( M_f \) and \( M_g \). Since \( V \) is compact, \( M_{p_n}V \) converges in norm to \( M_fV \), and \( M_fVM_{q_n} \) converges in norm to \( M_fVM_g \). Thus \( f \otimes g^* \) belongs to the norm closed algebra generated by \( \{M_z, V\} \).

By Lemmas 3.7 and 3.8, all the finite rank operators of \( \mathcal{T}(\mathcal{H}) \) belong to the norm closed algebra of \( \{M_z, V\} \). By the Erdos Density Theorem 3.11, the unit ball is strongly dense in the unit ball of \( \mathcal{T}(\mathcal{H}) \).

Notes and Remarks.

The invariant subspaces of \( V \) have been found by Dixmier [1], Donoghue [1], and Brodskii [1]. The usual proof makes use of Titchmarsh's Theorem on the zero divisors in the convolution algebra \( L^1(0,1) \). Theorem 5.4 and this approach to the Volterra operator \( V \) due to Livsic [1]. Gohberg and Krein [2] show how Titchmarsh's Theorem can be deduced from this (see Exercise 5.4). Another approach to \( \text{Lat}(V) \) is given by Sarason [4]. Theorem 5.10 is also due to Sarason, but the proof given here is due to Erdos [11]. Theorem 5.12 is in Sarason [3], and is a consequence of more general results of Radjavi-Rosenthal [1] and Arveson [6] on weakly closed algebras with a nest of invariant subspaces (see Chapter 15).
Exercises.

5.1 Verify that $V^m f(x) = \int_0^x f(t)(x-t)^{n-1}/(n-1)! \, dt$.

5.2 Let $\{e_n, n \geq 1\}$ be an orthonormal basis of $\mathcal{H}$. Let $D$ be any diagonal self-adjoint operator with respect to the basis $\{e_n\}$ with distinct eigenvalues. Let $y = \sum_{n=1}^{\infty} a_n e_n$ be a unit vector such that $a_n \neq 0$ for all $n \geq 1$. Set $T = \frac{1}{2} y \otimes y^* + iD$. Then $T + T^* = y \otimes y^*$ is a rank one projection. Prove that $T$ is irreducible and hence completely non-normal. Compare this with Theorem 5.4.

5.3 (Donoghue) Let $\{e_n, n \geq 1\}$ be an orthonormal basis for $\mathcal{H}$. Let $A$ be the weighted shift given by $A e_0 = 0$ and $A e_n = 2^{-n} e_{n-1}$ for $n \geq 1$.

(i) Show that $\text{Lat} A$ is the nest $\mathcal{P} = \{P_n, n \geq 0\}$ where $P_n = \text{span}\{e_k | 0 \leq k \leq n\}$.

Hint: If $x = \sum_{n=0}^{\infty} a_n e_n$ is not in any $P_n$ and $|a_M| \geq |a_k| \text{ for } k \geq M$, show that $a_M^{-1} 2^{M(M+1)/2} A^M x = e_0 + \sum_{j=1}^{\infty} \beta_j e_j$ and $|\beta_j| \leq 2^{-Mj}$.

(ii) If $p(x) = \sum_{k=0}^{n} a_k x^k$, show that $\|p(A)\|_2 \leq 3^{-n} \|p(A^*) e_0\|$. Hence show that $\{A\}'$ is the norm closed algebra generated by $A$ and $I$.

(iii) Let $D$ be a diagonal matrix with distinct eigenvalues. Show that the weakly closed algebra generated by $A$ and $D$ is $\overline{T(\mathcal{P})}$.

5.4 Recall that $L^1(0,1)$ is a Banach algebra under the convolution product

$$f * g(x) = \int_0^x f(x-t) g(t) \, dt$$.

Prove the Titchmarsh Convolution Theorem: If $f$ and $g$ belong to $L^1(0,1)$ and $f * g = 0$, then there is an $\alpha$ in $[0,1]$ such that $\text{supp} f \subseteq [\alpha, 1]$ and $\text{supp} g \subseteq [1-\alpha, 1]$. Hint: If $f$ and $g$ are continuous (and hence in $L^2$), show that $(V^m f) * g = 0$ for all $n \geq 0$.

10. Derivations of $C^*$-Algebras
11. M-Ideals
12. Quasitriangular Algebras
13. Similarity and Approximate
    Unitary Equivalence
6. The Radical

In the study of any Banach algebra, one is interested in its representation theory. In this section, sufficiently many representations are constructed to fully describe the (Jacobson) radical $\mathcal{R}$ and the quotient algebra $\mathcal{T}(\mathcal{N})/\mathcal{R}$.

The first step is a description of $C^*(\mathcal{N})$, the $C^*$-algebra generated by $\{P(N) : N \in \mathcal{N}\}$. Since the product $\prod_{i=1}^n P(N_i) = P(\bigwedge_{i=1}^n N_i)$, $C^*(\mathcal{N})$ is the closed linear span of $\{P(N) : N \in \mathcal{N}\}$. It is abelian, and thus it is $*$-isomorphic to $C(M_{\mathcal{N}})$ where $M_{\mathcal{N}}$ is its maximal ideal space. Let $2$ denote the two element lattice $\{0,1\}$. $\text{Hom}(\mathcal{N},2)$ denotes the set of lattice homomorphisms of $\mathcal{N}$ onto $2$. This set has a natural order given by $\phi \leq \psi$ if and only if $\phi(N) \leq \psi(N)$ for all $N$ in $\mathcal{N}$. $\text{Hom}(\mathcal{N},2)$ is endowed with the order topology, which is the smallest topology such that $L_\phi = \{\psi : \psi < \phi\}$ and $U_\phi = \{\psi : \psi > \phi\}$ are open.

6.1 Proposition. There is a canonical homeomorphism of the maximal ideal space $M_{\mathcal{N}}$ of $C^*(\mathcal{N})$ onto $\text{Hom}(\mathcal{N},2)$ given by restriction to $P(\mathcal{N})$.

Proof. Let $\phi$ belong to $M_{\mathcal{N}}$. Then $\phi(P(N)) = \phi(P(N))^2$, and thus equals 0 or 1. Also, this is an increasing function of $N$. Hence $\bar{\phi}(N) = \phi(P(N))$ is a lattice homomorphism onto $2$. Conversely, for $\phi$ in $\text{Hom}(\mathcal{N},2)$, one defines $\phi(P(N)) = \phi(N)$. Extend $\phi$ by linearity to the span $P(\mathcal{N}) : N \in \mathcal{N}$. Let $A$ be a finite linear combination of $P(N_i)$, $1 \leq i \leq n$. Order them so that $0 = N_0 < N_1 < N_2 < ... < N_n = 1$. and set $E_i = P(N_i) - P(N_{i-1})$. The $A$ can be written as $\sum_{i=1}^n a_i E_i$. There will be an integer $i_0$ so that $\bar{\phi}(N_{i_0}) = 1 > \bar{\phi}(N_{i_0-1})$, and hence $\phi(E_{i_0}) = 1$ and $\phi(E_i) = 0$ otherwise. So

$$|\phi(A)| = |a_{i_0}| \leq \|A\|.$$

Hence $\phi$ extends to a continuous functional on $C^*(\mathcal{N})$. It is clear that $\phi$ is uniquely determined by $\bar{\phi}$, and thus a bijective correspondence is established.

The map $\Phi$ taking $\phi$ to $\bar{\phi}$ is a bijection of the compact Hausdorff space $M_{\mathcal{N}}$ onto the Hausdorff space $\text{Hom}(\mathcal{N},2)$. Thus once it is established that this map is continuous, it will follow that it is a homeomorphism.
\[ N_\phi = \sup \{ N \in \mathcal{N} : \tilde{\phi}(N) = 0 \} \]

If \( \tilde{\phi}(N_\phi) = 0 \), then \( \tilde{\phi}(N) = 0 \) if and only if \( N \leq N_\phi \). So
\[
U_\phi = \{ \tilde{\psi} > \tilde{\phi} \} = \{ \tilde{\psi} : \tilde{\psi}(N_\phi) = 1 \}
\]

and
\[
L_\phi = \{ \tilde{\psi} < \tilde{\phi} \} = \{ \tilde{\psi} : N_\phi > N \} = \bigcup_{N < N_\phi} \{ \tilde{\psi}(N) = 1 \}
\]

Similarly, if \( \tilde{\phi}(N_\phi) = 1 \), then \( \tilde{\phi}(N) = 0 \) if and only if \( N < N_\phi \). And
\[
U_\phi = \{ \tilde{\psi} > \tilde{\phi} \} = \{ \tilde{\psi} : N_\phi < N \} = \bigcup_{N < N_\phi} \{ \tilde{\psi}(N) = 1 \}
\]

and
\[
L_\phi = \{ \tilde{\psi} < \tilde{\phi} \} = \{ \tilde{\psi} : \tilde{\psi}(N_\phi) = 0 \}
\]

Now \( \Phi^{-1}(\{ \tilde{\psi}(\tilde{\psi}(N) = 0) = \{ \psi : \psi(P(N)) < 1/2 \} \) is open in the weak* topology on \( M_\mu \). Likewise,
\[
\Phi^{-1}(\{ \tilde{\psi}(\tilde{\psi}(N) = 1) \} = \{ \psi : \psi(P(N)) > 1/2 \}
\]

is open. So \( \Phi^{-1}(U_\phi) \) and \( \Phi^{-1}(L_\phi) \) are open for all \( \tilde{\phi} \) in \( Hom(\mathcal{N}, 2) \). Thus \( \Phi \) is continuous, and hence a homeomorphism. \( \blacksquare \)

**6.2.** There is a natural parametrization of \( M_\mu \) implicit in the proof above. For \( \phi \) in \( M_\mu \), set \( \epsilon_\phi = 1 - \tilde{\phi}(N_\phi) \). The set \( X_\mu = \{ (N_\phi, \epsilon_\phi) : \phi \in M_\mu \} \) is a subset of \( \mathcal{N} \times \{0,1\} \). Let \( < \) be the lexicographic order on \( X_\mu \):
\[
(N_1, \epsilon_1) < (N_2, \epsilon_2) \text{ if } (N_1 < N_2) \text{ or } (N_1 = N_2, \text{ and } \epsilon_1 < \epsilon_2)
\]

The pair \( (N_\phi, \epsilon_\phi) \) determines \( \tilde{\phi} \) (and thus \( \phi \)) by the rule
\[
\tilde{\phi}(N) = 0 \text{ if and only if } (N, 0) < (N_\phi, \epsilon_\phi)
\]

The sets \( L_\phi \) and \( U_\phi \) become
\[
L_\phi = \{ \tilde{\psi} : (N_\phi, \epsilon_\phi) > (N, \epsilon) \}
\]

and
\[
U_\phi = \{ \tilde{\psi} : (N_\phi, \epsilon_\phi) < (N, \epsilon) \}
\]

So the map taking \( \phi \) to \( (N_\phi, \epsilon_\phi) \) is order reversing.

Every pair \( (N, \epsilon) \) in \( \mathcal{N} \times \{0,1\} \) gives rise to an increasing function of \( \mathcal{N}_1 \) into \( 2 \). If one deletes the pairs \( \{ 0 \}, 0 \) and \( \{ 0,1 \} \) because they imply \( \phi(0) = 1 \) and \( \phi(0) = 0 \) respectively, the remaining pairs determine an element \( \phi \) of \( Hom(\mathcal{N}, 2) \). Some duplication is possible. Consider first a pair \( (N, 1) \) determining \( \phi \) by (6.2.1). Then \( \phi(N) = 0 \) and \( \phi(N') = 1 \) for
$N' > N$. Thus $(N_\phi, \epsilon_\phi) = (N, 1)$. Now, consider $(N, 0)$. Then $\tilde{\psi}(N) = 1$ and $\phi(N') = 0$ for $N' < N$. Thus $N_\phi = N$. When $N = N_\phi$, $(N_\phi, \epsilon_\phi) = (N, 0)$. But when $N < N$, $(N_\phi, \epsilon_\phi) = (N, 1)$. In this case, $A = N \ominus N_\phi$ is an atom of $\mathcal{H}$ and $\phi$ is evaluation of this atom. Thus, one can think of $X_\phi$ as a quotient of $\mathcal{H} \times \{0, 1\} \setminus \{(0), 0\} \cup \{1\}$ by identifying $(N_\phi, 1)$ and $(N, 0)$ when $N_\phi \neq N$. When it is convenient to use this parametrization, we will write $\phi \equiv (N_\phi, \epsilon_\phi)$.

**6.3.** Let us associate to each $\phi$ in $M_\mathcal{H}$, the set $\mathcal{E}_\phi$ of projections $E = P(N_1) - P(N_2)$ with $N_1, N_2$ in $\mathcal{H}$ such that $\phi(E) = 1$. These projections will be called test intervals for $\phi$. By Theorem 2.15, the map $\Phi_\mathcal{H}(T) = ET|EH$ is an algebra homomorphism. For $\phi$ in $M_\mathcal{H}$, define a seminorm

$$||T||_\phi = \inf_\mathcal{E}_\phi ||ET - EH||$$

Let $I_\phi$ denote the set of operators $T$ in $\mathcal{T}(\mathcal{H})$ such that $||T||_\phi = 0$. It is easy to verify that

$$I_\phi = \bigcup_{E \in \mathcal{E}_\phi} \ker \Phi_\mathcal{H}.$$  

In particular, $I_\phi$ is a closed ideal. Let $D_\phi = \mathcal{T}(\mathcal{H})/I_\phi$, and let $\Phi_\phi$ denote the natural quotient map onto $D_\phi$. $I_\phi$ will be called a diagonal ideal, and $D_\phi$ its associated diagonal algebra.

Let us consider $\mathcal{E}_\phi$ more carefully. If $\phi$ is evaluation at an atom $A$, then $E_\phi = P(A)$ is the least element of $\mathcal{E}_\phi$. Thus $\Phi_\phi = \Phi_\mathcal{H}$ is the compression map onto $A$, and $D_\phi = B(A)$. If $\phi \equiv (N, 0)$ and $N = N_\phi$, then every test interval contains a smaller one of the form $P(N) - P(N')$ for $N' < N$. Thus

$$||T||_\phi = \inf_{N' < N} ||(P(N') - P(N))T(P(N) - P(N'))||$$

$$= \lim_{N' \downarrow N} ||\Phi_{N' \ominus N}(T)||.$$  

Similarly, if $\phi \equiv (N, 1)$ and $N = N_\phi$, then every test interval contains $P(N) - P(N)$ for some $N' > N$; and

$$||T||_\phi = \inf_{N' > N} ||(P(N') - P(N))T(P(N') - P(N))||$$

$$= \lim_{N' \uparrow N} ||\Phi_{N' \ominus N}(T)||.$$  

There is also a connection with the topology of $M_\mathcal{H}$. For each interval $E = P(N_1) - P(N_2)$, let
\[ O_E = \{ \phi \in M_N : E \in E_\phi \} = \{ \phi : \tilde{\phi}(N_1) = 1, \tilde{\phi}(N_2) = 0 \} = \{ \phi : \tilde{\phi}(N_1) > 1/2 > \tilde{\phi}(N_2) \} . \]

It is clear from the last two formulations that \( O_E \) is both open and closed in \( M_N \). Note that \( O_{E_1}, \ldots, O_{E_n} \) is a finite open cover of \( M_N \) if and only if \( \sum_{i=1}^n E_i \geq 1 \).

6.4. The (Jacobson) radical of a Banach algebra has a number of definitions. One convenient to our purposes is

\[ \text{rad}(\mathcal{A}) = \{ A \in \mathcal{A} : AB \text{ is quasinilpotent for all } B \in \mathcal{A} \} \]

\[ = \{ A \in \mathcal{A} : A \text{ is quasinilpotent for all } B \in \mathcal{A} \} . \]

It is also described as

\[ \bigcap \{ \ker \pi : \pi \text{ is an algebraically irreducible representation of } \mathcal{A} \} . \]

The equivalence of these notions may be found in any standard text on Banach algebras (cf. Bonsall-Duncan [1], III.17 or Rickart [1] 2.3.2). An algebra is called \textit{semi-simple} if its radical is \{0\}.

If \( \mathcal{F} \) is a finite nest, \( \mathcal{T}(\mathcal{F}) \) consists of block upper triangular \( n \times n \) matrices. If \( T \) in \( \mathcal{T}(\mathcal{F}) \) has zero diagonal \( \Delta(T) \), then \( AT \) is strictly upper triangular for every \( A \) in \( \mathcal{T}(\mathcal{F}) \). Thus \( (AT)^n = 0 \) and \( T \) belongs to the radical. Conversely, if \( \Delta(T) \neq 0 \), then \( \Delta(T)^* \) belongs to \( \mathcal{T}(\mathcal{F}) \). Then since \( \Delta(T)^*\Delta T \) is positive,

\[ \| (\Delta(T)^*T)^n \|^\frac{1}{n} \geq \| \Delta((\Delta(T)^*T)^n) \|^\frac{1}{n} = \| (\Delta(T)^*\Delta(T))^n \|^\frac{1}{n} = \| \Delta(T)^*\Delta(T) \| > 0 . \]

So \( \text{rad} \mathcal{T}(\mathcal{F}) = \{ T \in \mathcal{T}(\mathcal{F}) : \Delta(T) = 0 \} \).

If \( \mathcal{N} \) is an arbitrary nest and \( \mathcal{F} \) is a finite subnest of \( \mathcal{N} \), then

\[ \text{rad} \mathcal{T}(\mathcal{F}) \subseteq \mathcal{T}(\mathcal{N}) \subseteq \mathcal{T}(\mathcal{F}) . \]

Thus the previous argument implies that \( \text{rad} \mathcal{T}(\mathcal{F}) \subseteq \text{rad} \mathcal{T}(\mathcal{N}) \).

6.5 Lemma. Let \( T \) belong to \( \mathcal{T}(\mathcal{N}) \) and let \( \phi \) belong to \( M_N \). Then there is an operator \( A \) in the unit ball of \( \mathcal{T}(\mathcal{N}) \) such that

\[ \| (AT)^n \|_\phi = \| T \|_\phi^n \text{ for } n \geq 1 . \]

\textbf{Proof.} If \( \phi \) is evaluation at an atom \( E \), then let \( UP \) be the polar decomposition of \( \Phi_E(T) \). Then \( U^* \) belongs to \( \mathcal{T}(\mathcal{N}) \) and \( \Phi_E(U^*T) = P \) is positive. So
\[ \|(U^T)^n\|_\phi = \|P^n\| = \|P\|^n = \|T\|_\phi^n. \]

If \( \phi \equiv (N_0, 0) \), \( \|T\|_\phi = \lim_{N \uparrow N_0} \|\Phi_{N_0 \Theta N}(T)\| \). We may suppose that \( \|T\|_\phi > 0 \), and normalize so that \( \|T\|_\phi = 1 \). Now \( P(N_0) \) is the strong operator limit of \( P(N_\alpha) \) for \( N_\alpha < N \). Thus if \( N < N_0 \),

\[
1 \leq \|(P(N_0) - P(N))T(P(N_0) - P(N))\|
= \lim_{N_\alpha \uparrow N_0} \|(P(N_\alpha) - P(N))T(P(N_\alpha) - P(N))\|.
\]

So one may extract a sequence of elements of \( \mathcal{N} \), \( N_1 < N_2 < \ldots \) so that \( N_0 = \bigvee_{k \geq 1} N_k \) and

\[
\|(P(N_{k+1}) - P(N_k))T(P(N_{k+1}) - P(N_k))\| \geq 1 - 1/k
\]

for \( k \geq 1 \). Choose unit vectors \( x_k \) and \( y_k \) in \( N_{k+1} \ominus N_k \) so that

\[
(Tx_k, y_k) > 1 - 1/k.
\]

By Lemma 2.8, the rank one operator \( x_k \otimes y_k^* \) belongs to \( \mathcal{T}(\mathcal{N}) \) for each \( k \geq 1 \). Thus \( A = \sum_{k \geq 1} x_k \otimes y_k^* \) belongs to \( \mathcal{T}(\mathcal{N}) \) since it is the strong operator limit of the finite partial sums. Also \( \|A\| = 1 \).

Notice that \( AT \) maps \( N_{k+1} \ominus N_k \) into \( N_k \) for each \( k \geq 1 \), and

\[
(P(N_k) - P(N_{k-1}))ATx_{k+1} = (Tx_{k+1}, y_{k+1})x_k.
\]

Thus

\[
((AT)^2x_{k+2}, x_k) = (P(N_k))^{\perp}ATP(N_{k+2})x_{k+2}, x_k)
= (ATP(N_{k+1}))^{\perp}P(N_{k+2})ATx_{k+2}, x_k)
= (Tx_{k+2}, y_{k+2})(ATx_{k+1}, x_k)
= (Tx_{k+2}, y_{k+2})(Tx_{k+1}, y_{k+1})
> (1 - \frac{1}{k+2})(1 - \frac{1}{k+1}).
\]

By induction, one obtains

\[
((AT)^n x_{k+n}, x_k) \geq \prod_{j=1}^{n} 1 - \frac{1}{k+j}.
\]

If \( N < N_0 \), \( x_k \) belongs to \( N_0 \ominus N \) for all \( k \) sufficiently large. Hence

\[
\|\Phi_{N_0 \Theta N}(AT^n)\| \geq \lim_{k \to \infty} \prod_{j=1}^{n} 1 - \frac{1}{k+j} = 1.
\]

So
1 ≤ \|(AT)^n\|_\phi ≤ \|A\|^n\|T\|_\phi^n ≤ \|T\|_\phi ≤ 1

as desired. When \( \phi = (N_0,1)\), the proof is analogous.

6.6 Corollary The algebras \( D_\phi \) are semi-simple.

Proof. If \( T + I_\phi \neq 0 \), then with \( A \) as constructed in Lemma 6.5, \( AT + I_\phi \) is not quasinilpotent. □

6.7 Theorem. The following are equivalent for \( T \) in \( \mathcal{T}(\mathcal{N}) \).

1) \( T \) belongs to \( \text{rad} \mathcal{T}(\mathcal{N}) \).
2) \( T \) belongs to \( \bigcap \{ I_\phi \colon \phi \in M_N \} \).
3) \( T \) belongs to the closure of \( \bigcup \{ \text{rad} \mathcal{T}(\mathcal{F}) \colon \mathcal{F} \text{ finite nest of } \mathcal{N} \} \).
4) (Ringrose condition) For every \( \epsilon > 0 \), there is a finite nest \( \mathcal{F} \) of \( \mathcal{N} \) such that \( \|\Delta_\mathcal{F}(T)\| < \epsilon \).

Proof. If \( \|T\|_\phi > 0 \) for some \( \phi \), Lemma 6.5 provides an \( A \) in \( \mathcal{T}(\mathcal{N}) \) such that \( AT \) is not quasinilpotent. Thus 1) implies 2). Suppose 2) holds. For each \( \phi \) in \( M_N \), \( \|T\|_\phi = 0 \). Hence given \( \epsilon > 0 \), there is a test interval \( E_\phi \) in \( \mathcal{E}_\phi \) such that \( \|E_\phi TE_\phi\| < \epsilon \). The collection \( \{ O_\phi \colon \phi \in M_N \} \) is an open cover of \( M_N \). By compactness, there is a finite subcover \( O_{E_1}, \ldots, O_{E_n} \). Thus \( \sum_{i=1}^n E_i \geq I \). Let \( \mathcal{F} \) be the finite nest determined by the endpoints of these \( E_i \). Then

\[
\|\Delta_\mathcal{F}(T)\| \leq \max\|E_i TE_i\| < \epsilon .
\]

This proves 4). If \( T \) satisfies 4), then \( T - \Delta_\mathcal{F}(T) \) belongs to \( \text{rad} \mathcal{T}(\mathcal{F}) \). By hypothesis, there is a sequence \( \mathcal{F}_n \) such that \( \lim\|\Delta_{\mathcal{F}_n}(T)\| = 0 \), so \( T = \lim T - \Delta_{\mathcal{F}_n}(T) \). This establishes 3). But \( \text{rad} \mathcal{T}(\mathcal{N}) \) is a closed ideal containing each \( \text{rad} \mathcal{T}(\mathcal{F}) \), so 3) implies 1). □

6.8 Example. Let \( \mathcal{P} = \{ P_n \colon n \geq 0, \mathcal{N} \} \) be given by an increasing sequence of subspaces whose union is dense in \( \mathcal{N} \). Then \( M_P \) is isomorphic to \( \omega = \mathbb{N} \cup \{ \infty \} \), and \( \Phi_n \) is compression to the atom \( P_n \ominus P_{n-1} \) for \( n \geq 1 \). The other ideal is given by the seminorm

\[
\|T\|_\infty = \inf\|P(P_n)^\perp T\| .
\]

An operator \( T \) in \( \mathcal{T}(\mathcal{P}) \) belongs to \( \text{rad} \mathcal{T}(\mathcal{P}) \) if and only if \( \Delta(T) = 0 \) and \( \|T\|_\infty = 0 \).
6.9 Corollary. A compact operator $K$ in $\mathcal{T}(\mathcal{N})$ belongs to the radical if and only if $\Delta(K) = 0$.

Proof. Lemma 3.5 and the hypothesis $\Delta(K) = 0$ implies the Ringrose condition. The other implication is trivial.

Let $\mathcal{D}$ be the algebra of all bounded functions $(D_\phi)$ on $M_\mathcal{N}$ such that $D_\phi$ belongs to $\mathcal{D}_\phi$, with norm

$$||(D_\phi)|| = \sup_{\phi \in M_\mathcal{N}} ||D_\phi||_\phi.$$ 

Let $\Phi(T) = (\Phi_\phi(T))$ be the natural homomorphism of $\mathcal{T}(\mathcal{N})$ into $\mathcal{D}$, and let $\mathcal{D}_\mathcal{N}$ be the image of $\Phi$.

6.10 Theorem. For $T$ in $\mathcal{T}(\mathcal{N})$, the map $\phi \mapsto ||T||_\phi$ is upper semicontinuous. In particular, it is continuous at $\phi_0$ if $||T||_{\phi_0} = 0$. Furthermore,

$$\max_{\phi \in M_\mathcal{N}} ||T||_\phi = ||T + \text{rad} \mathcal{T}(\mathcal{N})||.$$ 

Thus $\mathcal{T}(\mathcal{N})/\text{rad} \mathcal{T}(\mathcal{N})$ is isometrically isomorphic to $\mathcal{D}_\mathcal{N}$.

Proof. For each $\phi$ in $M_\mathcal{N}$, and $\epsilon > 0$, there is a test interval $E_\phi$ in $E_\phi$ such that $||ETE|| < ||T||_\phi + \epsilon$. Thus $||T||_\psi < ||T||_\phi + \epsilon$ for all $\psi$ in $O_{E_\phi}$. Hence $\phi \mapsto ||T||_\phi$ is upper semicontinuous. Consequently, if $||T||_{\phi_0} = 0$, this function is continuous at $\phi_0$. It also follows that $\max ||T||_\phi$ is attained at some $\phi_0$.

By Theorem 6.7, $||R||_\phi = 0$ if $R$ belongs to the radical. Thus

$$||T||_\phi = \inf ||T + R||_\phi : R \in \text{rad} \mathcal{T}(\mathcal{N}) \leq ||T + \text{rad} \mathcal{T}(\mathcal{N})||.$$ 

So the map of $\mathcal{T}(\mathcal{N})/\text{rad} \mathcal{T}(\mathcal{N})$ into $\mathcal{D}$ is contractive. On the other hand, the collection $\{O_{E_\phi} : \phi \in M_\mathcal{N}\}$ constructed in the first paragraph is an open cover of $M_\mathcal{N}$. As in the proof of Theorem 6.7, a finite subcover yields a finite nest $\mathcal{F}$ such that

$$||\Delta_\mathcal{F}(T)|| < \max ||T||_\phi + \epsilon.$$ 

Since $T - \Delta_\mathcal{F}(T)$ belongs to $\text{rad} \mathcal{T}(\mathcal{N})$,

$$||T + \text{rad} \mathcal{T}(\mathcal{N})|| \leq ||\Delta_\mathcal{F}(T)|| < \max ||T||_\phi + \epsilon.$$ 

Hence the map of $\mathcal{T}(\mathcal{N})/\text{rad} \mathcal{T}(\mathcal{N})$ into $\mathcal{D}$ is isometric.

As mentioned in section 6.4, the kernel of every algebraically irreducible representation contains the radical, and the intersection of these kernels equals the radical. A representation of a Banach algebra $\mathcal{A}$ on $\mathcal{X}$ is a
homo morphism $\pi$ of $A$ into $B(\mathcal{X})$. This is automatically continuous. The representation is topologically irreducible if the only closed invariant subspaces of $\pi(A)$ are $\{0\}$ and $\mathcal{X}$. Every algebraically irreducible representation of $A$ is equivalent to a continuous representation of $A$. It is not known, however, whether the kernel of every topologically irreducible representation is equal to the kernel of an algebraically irreducible one, or even that they contain the radical (cf. Bonsall-Duncan [1], III.25 or Rickart [1], 2.2.3). In the case of nest algebras, the situation is better.

6.11 Theorem. Let $\pi$ be a non-zero topologically irreducible representation of $\mathcal{T}(\mathcal{N})$ on a Banach space $\mathcal{X}$. Then $\ker\pi$ contains exactly one diagonal ideal $I_\phi$.

Proof. For $N$ in $\mathcal{N}$, let $P = \pi(P(N))$. Then $P = P^2$, and for all $T$ in $\mathcal{T}(\mathcal{N})$, one has

$$\pi(T)P = \pi(TP(N)) = \pi(P(N)TP(N)) = P\pi(T)P.$$ 

Thus $P$ is an idempotent such that $P\mathcal{X}$ is invariant for $\pi$. Thus $P$ equals 0 or $I$. Hence the restriction of $\pi$ to $\{P(N): N \in \mathcal{N}\}$ is an increasing function of $\mathcal{N}$ into $\{0, I\}$; namely, an element $\phi$ of $\text{Hom}(\mathcal{N}_\mathcal{N}, 2)$. Hence $\pi(E)^T = I$ for every $E$ in $\mathcal{E}_\phi$. So

$$\|\pi(T)\| = \|\pi(ETE)\| \leq \|\pi\||ETE||$$

for $E$ in $\mathcal{E}_\phi$. Whence $\|\pi(T)\| \leq \|\pi\||T||_\phi$. In particular, $\ker\pi$ contains $I_\phi$ and $\pi$ factors through $D_\phi$.

If $\psi$ is another element of $\text{M}_{\mathcal{N}_\mathcal{N}}$, there is a test interval $E$ in $\mathcal{E}_\phi$ which is not in $\mathcal{E}_\psi$. Thus $\|E\|_\psi = 0$. So for every $T$ in $\mathcal{T}(\mathcal{N})$, $ETE$ belong to $I_\phi$ and $T^TETE$ belongs to $I_\psi$. Hence $I_\phi + I_\psi = \mathcal{T}(\mathcal{N})$. Therefore, since $\pi$ is not zero, $\ker\pi$ does not contain $I_\phi$ for $\psi \neq \phi$. \hfill $\blacksquare$

6.12 Corollary. The kernel of every topologically irreducible representation of $\mathcal{T}(\mathcal{N})$ contains the radical.

6.13 Theorem. The centre of each diagonal algebra $D_\phi$ consists of the scalar multiples of the identity.

Proof. If $\phi$ is evaluation at an atom $A$, then $D_\phi = B(A)$ which has trivial centre. So consider $\phi \equiv (N_0, 0)$ when $(N_0)_+ = N_0$. The case $\phi \equiv (N_0, 1)$ is handled similarly. The proof is a more sophisticated version of Lemma 6.5. If $T + I_\phi$ is not scalar, then since $\lambda \mapsto ||T^T - \lambda I||_\phi$ is continuous and $\{\lambda: |\lambda| \leq 2||T||\}$ is compact,

$$\sigma = \inf\{||T^T - \lambda I||_\phi: |\lambda| \leq 2||T||\} > 0.$$ 

Let $\{\lambda_j: j \geq 1\}$ be a dense subset of $\{\lambda: |\lambda| \leq 2||T||\}$. As in Lemma 6.5, if $N < N_0$ and $n$ is an integer, one can find an $N' < N_0$ so that
\[ \| \Phi_{N' \ominus N}(T - \lambda_j I) \| > \sigma/2 \text{ for } 1 \leq j \leq n. \]

Hence one may choose unit vectors \( x_j, y_j \) in \( N' \ominus N \) so that
\[ P(N' \ominus N) (T - \lambda_j I) x_j = \alpha_j y_j \quad \text{and} \quad \alpha_j > \sigma/2 \text{ for } 1 \leq j \leq n. \]

Recursively choose \( N_1 < N_2 < \ldots \) in \( \mathcal{N} \) with \( N_0 = \bigvee_{k \geq 1} N_k \) and unit vectors \( x_j^{(k)}, y_j^{(k)} \) in \( N_{k+1} \ominus N_k \) such that
\[ P(N_{k+1} \ominus N_k) (T - \lambda_j I) x_j^{(k)} = \alpha_j^{(k)} y_j^{(k)} \quad \text{and} \quad \alpha_j^{(k)} > \sigma/2 \text{ for } 1 \leq j \leq k. \]

Let \( z_k \) be any unit vector in \( N_{k+1} \ominus N_k \), and let \( \lambda \) be a cluster point of \( \{(T z_k, z_k), k \geq 1\} \). Drop to a subsequence \( k' \) so that \( \lambda = \lim (T z_{k'}, z_{k'}) \).

Relabel the subsequences as \( N_k, x_j^{(k)}, y_j^{(k)}, \) and \( z_k \) for \( k \geq 1 \). Choose a sequence \( j_k \leq k \) so that \( \lambda_{j_k} \) converges to \( \lambda \). Define \( A = \sum_{k \geq 1} x_{j_k}^{(k)} \otimes z_{k+1}^{(k)}. \)

This belongs to \( \mathcal{T}(\mathcal{N}) \) since each \( x_{j_k} \otimes z_{k+1}^{(k)} \) belongs by Lemma 2.3. Then \( A \) maps \( N_{k+1} \ominus N_k \) into \( N_k \ominus N_{k-1} \). Write \( E_k \) for \( P(N_{k+1}) - P(N_k) \). One computes
\[ E_k (AT - TA) z_{k+1} = (T z_{k+1}, z_{k+1}) x_{j_k}^{(k)} - E_k T z_{j_k}^{(k)} = \left[ (T z_{k+1}, z_{k+1}) - \lambda_{j_k} \right] x_{j_k}^{(k)} - \alpha_{j_k}^{(k)} y_{j_k}. \]

Now the first term tends to zero, and \( \alpha_{j_k}^{(k)} > \sigma/2 \) for all \( k \). Thus for all \( k \) sufficiently large, \( \|(AT - TA) z_{k+1}\| > \sigma/2 \). Every test interval for \( \phi \) contains most of the \( z_k \). Hence \( \|AT - TA\|_\phi > \sigma/2 \), and \( T \) is not central.

Let \( \Phi = \bigoplus \Phi_\phi \) denote the homomorphism of \( \mathcal{T}(\mathcal{N}) \) onto \( \mathcal{D}_\mathcal{N} \). Let \( Z(\mathcal{D}_\mathcal{N}) \) denote its centre.

**6.14 Theorem.** For \( T \) in \( \mathcal{T}(\mathcal{N}) \), the following are equivalent.

1) \( T \) belongs to \( C^*(\mathcal{N}) + \text{rad} \mathcal{T}(\mathcal{N}) \).

2) \( \Phi(T) \) belongs to \( Z(\mathcal{D}_\mathcal{N}) \).

2') \( T + \text{rad} \mathcal{T}(\mathcal{N}) \) belongs to \( Z(\mathcal{T}(\mathcal{N})/\text{rad} \mathcal{T}(\mathcal{N})) \).

3) \( \Phi_\phi(T) \) is scalar for every \( \phi \) in \( M_\mathcal{N} \).

4) \( \Phi_\phi(T) \) is a continuous, scalar valued function of \( \phi \).
Proof. Let $E = P(N_1)-P(N_2)$ for $N_2 < N_1$ in $\mathcal{N}$. Then if $E$ belongs to $\mathcal{E}_\Phi$, $\Phi_\phi(E) = \Phi_\phi(I) = I$. And if $E$ does not belong to $\mathcal{E}_\Phi$, there is a test interval in $F$ in $\mathcal{E}_\Phi$ orthogonal to $E$; so $\Phi_\phi(E) = 0$. Thus $\Phi(E)$ is scalar valued, and is the characteristic function of the closed and open set $O_E$. Hence $\Phi_\phi(E)$ is continuous. This extends to the closed linear span of these intervals, namely $C'(\mathcal{N})$. Since $\Phi$ annihilates the radical, this proves 1) implies 4).

Clearly, 4) implies 3) and 3) implies 2). Theorem 6.10 shows that 2) and 2') are equivalent. For $\Phi(T)$ to belong to the centre of $D_\mathcal{N}$, it is necessary and sufficient that $\Phi_\phi(T)$ belong to the centre of $D_\phi$ for each $\phi$ in $M_\mathcal{N}$. Thus Theorem 6.13 shows that 2) implies 3). Suppose 3) holds, let $\phi_0$ belong to $M_\mathcal{N}$, and let $\lambda I_0 = \Phi_\phi_0(T)$. Then $\|T-\lambda_0 I\|_{\phi_0} = 0$. By Theorem 6.10,

$$\phi \rightarrow \|T-\lambda_0 I\|_{\phi} = \|\Phi_\phi(T)-\Phi_\phi_0(T)\|_{\phi}$$

is continuous at $\phi_0$. Thus $\Phi_\phi_0(T)$ is a continuous function.

If 4) holds, $t(\phi) = \Phi_\phi(T)$ is a continuous function on $M_\mathcal{N}$. Hence there is an operator $A$ in $C'(\mathcal{N})$ such that $\Phi_\phi(A) = \Phi_\phi(T)$ for all $\phi$ in $M_\mathcal{N}$. Hence $T-A$ belongs to $ker\Phi = rad\ T(\mathcal{N})$. So 4) implies 1).

Finally, we show that the algebras $D_\phi$ can be represented isometrically as operator algebras on Hilbert space.

6.15 Theorem. There is an isometric isomorphism of $D_\phi$ into $B(\mathcal{K})$ for some Hilbert space $\mathcal{K}$.

Proof. If $\phi$ is evaluation at an atom $A$, then $D_\phi = B(A)$, and we are done. Suppose that $\phi \equiv (N_0,0)$ where $N_0 = (N_0)_\omega$. The case $\phi \equiv (N_0,1)$ with $N_0 = (N_0)_+$ is analogous. Choose an increasing sequence $N_1 < N_2 < \ldots$ in $\mathcal{N}$ with $N_0 = \bigvee_{k \geq 1} N_k$. Let $E_k = P(N_0)-P(N_k)$. Fix $\omega$ to be any non-zero multiplicative linear functional on $\ell^\infty$ such that $\omega$ annihilates $c_0$.

Let $X$ be the set of all bounded sequences $\{x_k\}$ such that $x_k$ belongs to $N_0 \subseteq N_k = E_k \mathcal{N}$. Define a sesquilinear form on $X$ by

$$\langle \vec{x}, \vec{y} \rangle_\omega = \omega((\{x_k,y_k\}))$$

Let $X_0$ be the set of all $\vec{x}$ in $X$ such that $\langle \vec{x}, \vec{x} \rangle_\omega = 0$. Then $X/X_0$ is an inner product space. Let $K$ be its Hilbert space completion. For $T$ in $T(\mathcal{N})$, define $T^{(\infty)}$ on $X$ by $T^{(\infty)}(x_k) = \{Tx_k\}$. Then since $\omega$ is a positive linear functional,

$$\|T^{(\infty)} \vec{x}\|_\omega^2 = \omega(\|Tx_k\|^2) \leq \|T\|^2 \omega(\|x_k\|^2) = \|T\|^2 \|\vec{x}\|_\omega^2$$

Thus $T^{(\infty)}$ maps $X_0$ into itself, and hence determines an operator $T^*$ on $K$.  

with \( \| \overline{T} \| \leq \| T \| \). Furthermore, for \( k \geq n \),

\[
\| Tx_k \| = \| E_k T E_n x_k \| \leq \| E_n T E_n \| \| x_k \| .
\]

Thus

\[
\| T^{(\infty)} \|_\omega \leq \| E_n T E_n \| \| x \|_\omega
\]

for all \( n \). It follows that \( \| T^{(\infty)} \|_\omega \leq \| T \|_\phi \| x \|_\omega \). Hence \( \| \overline{T} \| \leq \| T \|_\phi \).

On the other hand, let \( x_k \) be a unit vector in \( N_0 \ominus N_k \) such that \( \| Tx_k \| > (1 - \frac{1}{k}) \| E_k T E_k \| \). Then

\[
\| T^{(\infty)}(x_k) \|_\omega^2 \geq \omega \{(1 - \frac{1}{k})^2 \| E_k T E_k \|^2 \} = \| T \|_\phi^2 .
\]

So \( \| \overline{T} \| \geq \| T \|_\phi \). Consequently, the map taking \( T + I_{\delta} \) to \( \overline{T} \) is isometric. It is clearly a homomorphism. Thus the theorem is established.

This construction never produces an irreducible representation (except for an atom). Let \( x_k \) be a unit vector in \( N_{k+1} \ominus N_k \), and let \( y_k \) be a unit vector in \( N_{k+1} \). Then \( \overline{x} = \{x_k\} \) and \( \overline{y} = \{y_k\} \) determine unit vectors in \( K \). Furthermore, \( \langle T x_k, y_k \rangle = 0 \) for all \( k \). Hence \( \langle \overline{T} \overline{x}, \overline{y} \rangle = 0 \) for all \( T \in T(K) \). Thus \( M = \overline{T K} : T \in T(K) \) is a proper invariant subspace for this representation of \( T(K) \).

Notes and Remarks.

The characterization of the radical (Theorem 6.7) is due to Ringrose [3]. He did not explicitly identify each \( \phi \) as an element of \( Hom(N,2) \). This is done in Hopenwasser [1] and Hopenwasser-Larson [1]. The connection between \( Hom(N,2) \) and \( M_K \) was known to a number of people. It is first used explicitly in Davidson [9] and Apostol-Davidson [1]. Ringrose also proved Theorems 6.10, 6.11 and 6.12. Theorems 6.13, 6.14 and 6.15 are due to Lance [1].

Exercises.

6.1 (Ringrose) Let \( \phi_1, \ldots, \phi_n \) be finitely many distinct points in \( M_K \). Given \( U_i \in P_{\phi_i}, 1 \leq i \leq n \), find \( T \) in \( T(K) \) such that \( \Phi_{\phi_i}(T) = U_i \) for \( 1 \leq i \leq n \).

6.2 (Lance) Let \( J \) be a right (left, or 2-sided) ideal of \( T(K) \) containing the radical. Let \( J_\phi = \Phi_{\phi}(J) \) for each \( \phi \) in \( M_K \).

(i) Show that \( J = \{ T \in T(K) : \Phi_{\phi}(T) \in J_\phi \ \text{for all} \ \phi \ \text{in} \ M_K \} \).

(ii) Deduce that \( T \) is invertible in \( T(K) \) if and only if \( \Phi_{\phi}(T) \) is invertible for all \( \phi \) in \( M_K \).

6.3 Let \( A \) be a positive invertible operator, and let \( N \) be the nest generated by the spectral subspaces \( E_A[0,t], t \geq 0 \).
(a) (Deddens) Show that \( T(\mathcal{M}) \) consists of all operators \( T \) such that
\[
\sup_{n \geq 0} ||A^n T A^{-n}|| < \infty.
\]

(b) (Erdős) Show that \( \text{rad} T(\mathcal{M}) \) consists of all operators \( T \) such that
\[
\lim_{n \to \infty} ||A^n T A^{-n}|| = 0.
\]

6.4* Is \( D_\phi \) primitive? That is, does \( D_\phi \) have a faithful irreducible representation?

6.5 (Hopenwasser, Larson) Let \( L \) be a complete lattice such that \( \{P(L) : L \in L\} \) is commutative (a C.S.L.) and let \( C'(L) \) be the C* algebra generated by these projections.

(i) Show that \( \text{Hom}(L, 2) \) is homeomorphic to the maximal ideal space of \( C'(L) \).

(ii) For each \( \phi \) in \( \text{Hom}(L, 2) \), let \( E_\phi \) consist of all interval projections of \( L \) such that \( \phi(E) = 1 \). Define an ideal \( I_\phi \) in \( \text{Alg} L \) as
\[
I_\phi = \{T \in \text{Alg} L : \inf_{E_\phi} ||ETE|| = 0\}.
\]

(iii) Show that for \( T \) in \( \text{Alg} L \), the following are equivalent:
1) \( T \) belongs to \( \bigcap \{I_\phi : \phi \in \text{Hom}(L, 2)\} \).
2) \( T \) belongs to the closure of \( \bigcup \{\text{rad}T(F) : F \text{ finite sublattice of } L\} \).
3) For every \( \epsilon > 0 \), there is a finite sublattice \( F \) of \( L \) such that \( ||\Delta_F(T)|| < \epsilon \).

(iv) Show that for every non-zero irreducible representation \( \pi \) of \( \text{Alg} L \), there is exactly one \( \phi \) such that \( I_\phi \subseteq \ker \pi \). Hence deduce that if \( T \) satisfies any of the conditions in (iii), then \( T \) belongs to \( \text{rad}(\text{Alg} L) \).

6.6* Is \( \text{rad}(\text{Alg} L) = \bigcap \{I_\phi : \phi \in \text{Hom}(L, 2)\} \) in question 6.5?
7. Unitary Invariants For Nests

7.1. We wish to distinguish nests by their spatial characteristics. Two nests $\mathcal{N}$ and $\mathcal{M}$ are unitarily equivalent if there is a unitary operator $U$ such that $U \mathcal{N} = \{UN : N \in \mathcal{N}\}$ equals $\mathcal{M}$. The map $\phi_U$ taking $N$ in $\mathcal{N}$ to $UN$ in $\mathcal{M}$ is clearly an order isomorphism of $\mathcal{N}$ onto $\mathcal{M}$. Thus if $\mathcal{N}$ and $\mathcal{M}$ are unitarily equivalent, they must have the same order type. Now consider two order $\omega$ nests (as in Example 2.3), $\mathcal{P} = \{P_n, n \geq 1, \mathcal{P}\}$ with $dimP_n = n$ and $\mathcal{Q} = \{Q_n, n \geq 1, \mathcal{Q}\}$ with $dimQ_n = 2n$. These fail to be unitarily equivalent because a unitary operator must preserve dimension.

A somewhat more subtle example are the two continuous nests $\mathcal{N}$ on $L^2(0,1)$ and $\mathcal{M}$ on $L^2((0,1)^2)$ given in Examples 2.4 and 2.5. Any unitary operator $U$ taking $\mathcal{N}$ onto $\mathcal{M}$ must carry $\mathcal{N}'$ onto $\mathcal{M}'$. But $\mathcal{N}' = \mathcal{N}''$ is abelian and $\mathcal{M}'$ is not abelian. Both these examples can be resolved by developing a notion of multiplicity for the abelian von Neumann algebras. This treatment is identical to the unitary invariants for self-adjoint operators. This is the content of Theorem 7.4.

7.2 Lemma. Let $f$ be a continuous scalar valued function on $\mathcal{N}$. Then $A = \int_{\mathcal{N}} f(N)dN$ is well defined as a Riemann sum.

Proof. We may restrict our attention to real valued functions. By Proposition 2.13, $\mathcal{N}$ is compact. So for every $\varepsilon > 0$, there is a finite partition $\mathcal{F}$ consisting of $\{0\} = F_0 < F_1 < \ldots < F_n = \mathcal{N}$ so that

$$|f(N) - f(N')| < \varepsilon \quad \text{for all} \quad F_i \leq N \leq N' \leq F_{i+1}.$$  

Thus if $L_f$ and $U_f$ denote the usual upper and lower Riemann sums,

$$U_f - L_f = \sum_{i=1}^{n}(f(N_i^+) - f(N_i^-))(F_i - F_{i-1})$$

where $f(N_i^+) = \max\{f(N) : F_{i-1} \leq N \leq F_i\}$ and $f(N_i^-) = \min\{f(N) : F_{i-1} \leq N \leq F_i\}$. Clearly, $\|U_f - L_f\| \leq \varepsilon$. Furthermore, as in scalar Riemann sums, if $\mathcal{F}$ contains $\mathcal{F}$, then

$$L_\mathcal{F} \leq L_f \leq U_f \leq U_\mathcal{F}.$$  

Hence, $\lim_\mathcal{F} U_f = \lim_\mathcal{F} L_f = A$ exists.  \hfill $\blacksquare$
7.3. **Lemma.** Let \( \mathcal{N} \) be a nest on a separable Hilbert space. Then there is a self-adjoint operator \( A \) such that \( \{A\}'' = \mathcal{N}'' \) and \( \mathcal{N} = \{E_{A[0,t]} : 0 \leq t \leq 1\} \) where \( E_A \) is the spectral measure of \( A \).

**Proof.** By Proposition 2.13, there is an order preserving homeomorphism \( \Phi \) taking \( \mathcal{N} \) into the unit interval such that \( \Phi(0) = 0 \) and \( \Phi(1) = 1 \). Let

\[
A = \int_{\mathcal{N}} \Phi(N) dN
\]

where this is understood as a Reimann sum. By construction,

\[
E_A[0,t] = \Phi^{-1}(t)
\]

belongs to \( \mathcal{N} \) and every element of the nest occurs in this way. Also notice that \( E_A[0,t] = \Phi^{-1}(t)_- \) belongs to \( \mathcal{N} \) also.

Since \( A \) belongs to \( C'(\mathcal{N}) \), it belongs to \( \mathcal{N}'' \). On the other hand, \( \{A\}'' \) contains all the spectral projections of \( A \). Thus \( \{A\}'' = \mathcal{N}'' \). \( \blacksquare \)

7.4 **Theorem.** Let \( \mathcal{N} \) and \( \mathcal{M} \) be nests in separable Hilbert spaces. Let \( \Phi \) be an order preserving homeomorphism of \( \mathcal{N} \) into \([0,1] \). Suppose that \( \psi \) is an order isomorphism of \( \mathcal{N} \) onto \( \mathcal{M} \). Then there is a unitary operator \( U \) implementing \( \psi \) if and only if

\[
A = \int_{\mathcal{N}} \Phi(N) dN \text{ is unitarily equivalent to } B = \int_{\mathcal{M}} \Phi \circ \psi^{-1}(M) dM.
\]

**Proof.** If \( UN = \psi(N) \) for all \( N \) in \( \mathcal{N} \), then \( B' = UA^*U^* \) is a self-adjoint operation such that

\[
E_{B'}[0,t] = UE_A[0,t] = U \Phi^{-1}(t) = \psi \circ \Phi^{-1}(t) = E_B[0,t]
\]

for all \( t \). Thus \( B' = B \). Conversely, if \( B = UA^* \), the same identity reversed shows that \( UN = \psi(N) \) for all \( N \) in \( \mathcal{N} \). \( \blacksquare \)

7.5. Now we turn to the multiplicity theory of abelian von Neumann algebras. For convenience, we restrict our attention to separably acting algebras. These algebras are always generated by a single self-adjoint operator as in Lemma 7.3. To see this, note that since the unit ball of \( \mathcal{M} \) is compact and metrizable in the weak* topology, one can find a countable dense subset of the self-adjoint part. Replace this by their spectral projections \( \{E_n, n \geq 1\} \) corresponding to rational intervals. Let

\[
A = \sum_{n \geq 1} 3^{-n} E_n.
\]

Since \( \sum_{n \geq 2} 3^{-n} = 1/6 < 1/3 \), one obtains \( E_1 = E_A[1/3,1/2] \). Similarly, one finds that \( C'(A) \) contains \( \{E_n, n \geq 1\} \). Thus, \( \{A\}'' \) equals \( \mathcal{M} \).

Let \( X \) be the spectrum of \( A \). Then \( C'(A) \) is isomorphic to \( C(X) \) by the Gelfand theory. By the spectral theorem, there is a spectral measure \( E_A(\cdot) \) on Borel sets of \( X \), which is a countably additive, projection valued
measure such that
\[ f(A) = \int f(t) dE_A(t) \]
is defined for all bounded, Borel functions \( \text{Bor}(X) \). This functional calculus is a continuous \( * \)-representation of \( \text{Bor}(X) \) such that \( fg(A) = f(A)g(A) \), \( f(A)^* = f(A)^* \), and \( \| f(A) \| \leq \| f \|_{\infty} \). In particular, we obtain the following immediate corollary of Lemma 7.3.

7.6 **Corollary.** Let \( \Phi \) be an order preserving homeomorphism of \( \mathcal{M} \) onto a subset \( \omega \) of \([0,1]\). Then there is a spectral measure \( E_\omega \) on the Borel subsets of \( \omega \) such that \( E_\omega[0,t] = \Phi(\Phi^{-1}(t)) \).

7.7 **Lemma.** If \( f_n \) is a bounded sequence in \( \text{Bor}(X) \) converging pointwise to \( f \), then \( f_n(A) \) converges weakly to \( f(A) \). Consequently, \( C^*(A) \) is weakly dense in the image of \( \text{Bor}(X) \) which is contained in \( \mathcal{M} \).

**Proof.** Let \( x, y \) be vectors in \( \mathcal{M} \). Consider the scalar measure
\[ \mu_{x,y}(\cdot) = (E_A(\cdot)x,y) \]
By the Lebesgue Dominated Convergence Theorem,
\[ \lim_{n \to \infty} (f_n(A)x,y) = \lim \int f_n(t)d\mu_{x,y}(t) = \int f(t)d\mu_{x,y}(t) = (f(A)x,y) \]
Hence \( f_n(A) \) converges weakly to \( F(A) \). Since every bounded Borel function on \( X \) is the pointwise limit of a bounded sequence of continuous functions, \( C^*(A) \) is weakly dense in the image. But the weak operator closure of \( C^*(A) \) is \( \mathcal{M} \), concluding the proof. \( \blacksquare \)

In fact, \( \text{Bor}(X) \) is taken onto \( \mathcal{M} \). This will follow from Corollary 7.9.

An abelian von Neumann algebra is called **multiplicity free** if its commutant is also abelian. The following theorem characterizes these algebras.

7.8 **Theorem.** Let \( \mathcal{M} \) be an abelian von Neumann algebra, and let \( A \) be a self-adjoint operator such that \( \mathcal{M} = W^*(A) \). The following are equivalent:
1) \( \mathcal{M} \) is multiplicity free.
2) \( \mathcal{M} \) has a cyclic vector.
3) \( \mathcal{M} \) is maximal abelian.
4) \( \mathcal{M} \) is unitarily equivalent to the algebra \( L^\infty(\mu) \) acting by multiplication on \( L^2(\mu) \), where \( \mu \) is a regular Borel measure on \( X = \sigma(A) \).
Proof. 1) implies 2) follows from Proposition 2.13 applied to $\mathcal{M}$. Next, we show that 2) implies 4). Let $x$ be a unit cyclic vector and define the state $\tau(M) = (Mx,x)$ for $M$ in $\mathcal{M}$. The restriction of $\tau$ to $C^*(A)$ is a positive linear functional of norm one. By the Riesz Representation Theorem, there is a regular Borel measure $\mu$ (with $\|\mu\| = 1$) such that

$$\tau(f(A)) = \int f d\mu$$

for a $f$ in $C(X)$.

Define a linear map $U: C(X)$ into $\mathcal{H}$ by $Uf = f(A)x$. Then

$$(Uf, Ug) = (f(A)x, g(A)x) = ((\bar{g}f)(A)x, x) = \tau(\bar{g}f) = \int f \bar{g} d\mu.$$

Hence $U$ extends to an isometry of $L^2(\mu)$ onto the closure of $\{f(A)x : f \in C(X)\}$. Thus contains, in particular, $Mx$ for all $M$ in $\mathcal{M}$ since $C^*(A)$ is strongly dense. But $x$ is cyclic for $\mathcal{M}$, and hence $U$ is unitary. Furthermore, for $f$ and $g$ in $C(X)$,

$$UM_xU^*f(A)x = UM_xf = Ugf = g(A)(f(A)x).$$

Hence $UM_xU^* = g(A)$ for all $g$ in $C(X)$.

Since conjugation by $U$ carries $C^*(M_x)$ onto $C^*(A)$, it carries the weak closure of $C^*(M_x)$ onto $\mathcal{M}$. It suffices to show that this algebra is multiplication by $L^\infty(\mu)$. By Lemma 7.7, $M_f$ belongs to $C^*(M_x)^w$ for every bounded Borel function. Since $x$ is a separating vector for $\mathcal{M}$, $U^*x = 1$ is a separating vector for $C^*(M_x)^w$. If $f = 0$ a.e. $(\mu)$, then

$$\|M_1\|_2 = (M_f, \mu 1, 1) = \int |f|^2 d\mu = 0.$$

So the map taking $g$ in $L^\infty(\mu)$ to $M_g$ is well defined. On the other hand, suppose that $T$ commutes with $M_x$. Let $g = T1$. For every $f$ in $C(X)$,

$$Tf = T(M_f 1) = M_f T1 = fg = M_g f.$$

But $T$ is continuous, and $C(X)$ is dense in $L^2(\mu)$, so this extends to all of $L^2(\mu)$. If $r < \|g\|_\infty$, let $y$ be the characteristic function of $E = \{x : |g(x)| > r\}$. Then

$$\|T\|^2 \geq \|Ty\|^2 \|y\|^2 = \int_E |g|^2 d\mu / \mu(E) \geq r^2.$$

Thus $g$ belongs to $L^\infty(\mu)$. So $L^\infty(\mu) \subseteq C^*(M_x)^w \subseteq C^*(M_x)' \subseteq L^\infty(\mu)$.

This also proves that 4) implies 3). Finally, 3) implies 1) is trivial. ■

7.9 Corollary. Let $\mathcal{M}$ be an abelian von Neumann algebra on a separable Hilbert space. Then there is a regular Borel measure $\mu$ on $\mathbb{R}$ such that $\mathcal{M}$ is *-isomorphic to $L^\infty(\mu)$. 
Proof. By Proposition 2.12, $\mathcal{M}$ has a separating vector $x$. Let $\mathcal{M}_0$ be the restriction of $\mathcal{M}$ to the invariant subspace $\mathcal{H}_x$ which is the closed span of \{ $Mx : M \in \mathcal{M}$ \}. The restriction map taking $\mathcal{M}$ to $\mathcal{M}|\mathcal{H}_x$ is a $*$-homomorphism. It is one to one since $x$ is a separating vector, and thus it is a $*$-isomorphism. Clearly, $x$ is a cyclic vector for $\mathcal{M}_0$. Thus by Theorem 7.8, there is a regular Borel measure $\mu$ such that $\mathcal{M}_0$ is unitarily equivalent to $L^\infty(\mu)$.

7.10. It follows from this corollary that given a spectral measure $E$ on the real line, one can find a scalar spectral measure mutually absolutely continuous to $E$. That is, if $E$ is a spectral measure for $\mathcal{M}$ and $\mu$ is the measure constructed above, then $\mu(A) = 0$ if and only if $E(A) = 0$. The measure $\mu$ is determined up to its measure class $[\mu] = \{ \nu : \nu \sim \mu \}$ since if $\nu \sim \mu$, the $L^\infty(\nu) = L^\infty(\mu)$. So given a nest $\mathcal{N}$ of order type $\aleph$, one can talk about the measure class of the spectral measure.

7.11. For any cardinal $1 \leq n \leq \aleph_0$, a collection \{ $U_{ij}, 0 \leq i, j < n$ \} of partial isometries are called \{ $(n \times n)$ matrix units \} provided that $U_{ij} U_{kl} = \delta_{jk} U_{il}$ for all $i,j,k,l$ and $\sum_{i<i} U_{ii} = I$. An abelian von Neumann algebra $\mathcal{M}$ has uniform multiplicity $n$ if $\mathcal{M'}$ contains a system \{ $U_{ij}, 0 \leq i, j < n$ \} of $n \times n$ matrix units such that $\mathcal{M}_0 = \mathcal{M} | \mathcal{H}_0^\mathcal{H}$ is multiplicity free. Thus, $\mathcal{M}$ is unitarily equivalent to $\mathcal{M}_0^{(n)} = \{ A^{(n)} = A \oplus A \oplus \ldots \oplus A : A \in \mathcal{M}_0 \}$ acting on $\mathcal{H}_0^{(n)}$, the direct sum of $n$ copies of $\mathcal{H}_0 = U_{00} \mathcal{H}$. The unitary that does this is $\sum_{0 \leq i < n} U_{ii}$. This same unitary carries $\mathcal{M}_0^{(n)'}$ onto $\mathcal{M'}$, and $\mathcal{M}_0^{(n)'}$ is $\mathcal{M}_0 \otimes M_n(\mathbb{C})$, the algebra of $n \times n$ matrices with coefficients in $M_0$ acting on $\mathcal{H}_0^{(n)}$. If $n = \aleph_0$, replace $M_n(\mathbb{C})$ by $B(\mathcal{H})$.

7.12 Lemma. If $\mathcal{M}$ has uniform multiplicity, then the multiplicity is well defined.

Proof. Suppose $\mathcal{M}$ has uniform multiplicity $n$ and $m$ with $n \leq m$ and $n < \aleph_0$. By the remarks above, $\mathcal{M'}$ is unitarily equivalent to $\mathcal{M}_0^{(n)} \otimes M_m(\mathbb{C})$ and $\mathcal{M}_0^{(n)}$ is abelian. Thus if $\sigma$ is any multiplicative linear functional on $\mathcal{M}_0$, $\sigma \otimes id_n$ yields a non-zero $*$-homomorphism of $\mathcal{M}$ onto $M_m(\mathbb{C})$. Suppose that $\mathcal{M'}$ is also unitarily equivalent to $\mathcal{M}_1^{(n)} \otimes M_m(\mathbb{C})$. The restriction of $\sigma \otimes id$ to the subalgebra unitarily equivalent to $M_m(\mathbb{C})$ is a unital * homomorphism (thus not zero) of $M_m(\mathbb{C})$ (or $B(\mathcal{H})$ if $m = \aleph_0$) onto $M_m(\mathbb{C})$. This forces $m = n$ (because $M_m$ has no ideals and thus $\dim M_m = m^2 = n^2$; and $B(\mathcal{H})$ has only one ideal, $K$, of infinite codimension).
Let $\mathcal{M}$ be an abelian von Neumann algebra. Say that a non-zero projection $P$ in $\mathcal{M}$ has multiplicity $n$ if $\mathcal{M} | P\mathcal{H}$ has uniform multiplicity $n$.

7.13 Lemma. If $P$ is a projection of multiplicity $n$ in an abelian von Neumann algebra $\mathcal{M}$, then so does every non-zero projection $P' \leq P$. If $P_\alpha$ are projections in $\mathcal{M}$ of multiplicity $n$, so is $P = \sup P_\alpha$.

Proof. First, $\mathcal{M} | P\mathcal{H}$ is unitarily equivalent to $L^\infty(\mu)^{(n)}$. If $P' \leq P$, then $P'$ is unitarily equivalent to $M^{(n)}_\chi$ where $\chi$ is the characteristic function of a subset $X_0$ of $X$. Let $\mu' = \mu | X_0$. Clearly, $\mathcal{M} | P'\mathcal{H}$ is unitarily equivalent to $L^\infty(\mu')^{(n)}$, and thus has multiplicity $n$.

Let $P = \sup P_\alpha$. It is not difficult to write $P$ as an orthogonal direct sum $P = \sum_{k=1}^{\infty} P_k$ where $P_k \leq P_{\alpha_k}$ for some $\alpha_k$ (use separability). Each $P_k$ has multiplicity $n$ by the first paragraph. By Corollary 7.9, $\mathcal{M}$ is isomorphic to $L^\infty(\mu)$. So $\{P_k\}$ correspond to $M_{X_k}$ where $X_k$ are characteristic functions of pairwise disjoint sets $X_k$. Let $X_0 = \bigcup_{k=1}^{\infty} X_k$ and $\mu_k = \mu | X_k$ for $k \geq 0$. Then $\mathcal{M} | P_k\mathcal{H}$ is unitarily equivalent to $L^\infty(\mu_k)^{(n)}$ for all $k \geq 1$. By taking the direct sum, $\mathcal{M} | P\mathcal{H}$ is unitarily equivalent to $L^\infty(\mu_0)^{(n)}$, and thus has multiplicity $n$.

With this preparation, we can now state and prove the full classification theorem of (separably acting) abelian von Neumann algebras.

7.14 Theorem. Let $\mathcal{M}$ be a separably acting, abelian von Neumann algebra. Then there are pairwise orthogonal projections $P_n$ in $\mathcal{M}$, $1 \leq n \leq \aleph_0$ such that $P_n$ is of multiplicity $n$ in $\mathcal{M}$, and $\sum_{1 \leq n \leq \aleph_0} P_n = I$.

Let $A$ be a self-adjoint operator such that $\mathcal{M} = W^*(A)$. Then there are mutually singular measures $\mu_n$ on $X = \sigma(A)$, $1 \leq n \leq \infty$, so that $\mathcal{M}$ is unitarily equivalent to

$$L^\infty(\mu_{\infty})^{(\infty)} \oplus \sum_{n=1}^{\infty} \oplus L^\infty(\mu_n)^{(n)}$$

acting on $L^2(\mu_{\infty})^{(\infty)} \oplus \sum_{n=1}^{\infty} \oplus L^2(\mu_n)^{(n)}$.

Proof. For each cardinal $n$, $1 \leq n \leq \aleph_0$, Lemma 7.13 shows that the supremum $P_n$ of all projections $P_\alpha$ in $\mathcal{M}$ of multiplicity $n$ is the largest projection of multiplicity $n$. For $n \neq m$, $P_n P_m$ is a projection less than both $P_n$ and $P_m$. By Lemma 7.13, it has multiplicity both $n$ and $m$. By Lemma 7.12, $P_n P_m = 0$. So $\{P_n, 1 \leq n \leq \aleph_0\}$ are pairwise orthogonal. It must be shown that $\sum_{1 \leq n \leq \aleph_0} P_n = I$. Let $Q = I - \sum_{1 \leq n \leq \aleph_0} P_n$. 

Set $M_0 = M \mid Q \mathcal{H}$. If $Q \neq 0$, it suffices to find a projection $R$ in $M_0$ of uniform multiplicity. Recursively choose unit vectors $x_n$ and projections $Q_n$ onto $\{Mx_n : M \in M_0\}$ such that $\{Q_n, n \geq 1\}$ are pairwise orthogonal and $x_{n+1}$ is a separating vector for $M \vert (\sum_{i=1}^{n} Q_i) \perp \mathcal{H}$. The projections $Q_n$ belong to $M'$. Let $\overline{Q_n}$ denote the smallest projection in $M_0$ such that $\overline{Q_n} \geq Q_n$. (This is known as the central cover of $Q_n$.) Then $I = \overline{Q_1} \geq \overline{Q_n} \geq \overline{Q_{n+1}}$ for all $n \geq 1$. There are two cases: (i) there is an integers $n_0$ such that $\overline{Q_n} = I > \overline{Q_{n_0+1}}$, and (ii) $\overline{Q_n} = I$ for all $n \geq 1$.

In case (i), let $R = I - \overline{Q_{n_0+1}}$. Let $M_R = M \mid R \mathcal{H}$ and let $A_R = A \mid R \mathcal{H}$. So $M_R = M \mid R \mathcal{H}$ is isomorphic to $L^\infty(\mu)$, where $\mu$ is a Borel measure on $X_R = \sigma(A_R)$ via the isomorphism $\Phi(f) = f(A_R)$. Since $Rx_{n_0+1} = 0$ and $x_{n_0+1}$ is a separating vector for $M_0 \vert (\sum_{i=1}^{n_0} Q_i) \perp \mathcal{H}$, it follows that $R \leq \sum_{i=1}^{n_0} Q_i$. Let $R_i = RQ_i$ and $y_i = Rx_i$ for $1 \leq i \leq n_0$. Then $M_i = M \mid R_i \mathcal{H}$ has a cyclic vector $y_i$. By Theorem 7.8, there is a regular Borel measure $\mu_i$ on $X_R$ and a unitary $U_i$ of $L^2(\mu_i)$ onto $R_i \mathcal{H}$ such that

$$U_i M_f U_i^* = f(A_R) \mid R_i \mathcal{H}$$

for every bounded Borel function $f$. This implements a * isomorphism $\Phi_i$ of $L^2(\mu_i)$ onto $M_i$. Now $y_i$ is a separating vector for $M_R$. Thus, as in Corollary 7.9, the restriction map $\Psi_i(M) = M \mid R_i \mathcal{H}$ is a * isomorphism of $M_R$ onto $M_i$. Hence $\Phi_i^{-1} \circ \Psi_i \circ \Phi$ is a * isomorphism of $L^\infty(\mu)$ onto $L^\infty(\mu_i)$ which takes every Borel function $f$ to itself. Hence $\mu_i$ and $\mu$ are mutually absolutely continuous, whence $L^\infty(\mu_i) = L^\infty(\mu)$ for $1 \leq i \leq n_0$. So $U = \sum_{i=1}^{n_0} U_i$ carries $L^2(\mu)^{\oplus n}$ onto $R \mathcal{H} = \sum_{i=1}^{n_0} R_i \mathcal{H}$ and $UMU^* = f(A_R)$ for every $f$ in $L^\infty(\mu)$. Evidently, $M_R$ has uniform multiplicity $n$, contradicting the maximality of $P_n$.

Case (ii) is dealt with in a similar manner. In this case, $x_n$ is a separating vector for each $n$ and $\{Q_n, n \geq 1\}$ are pairwise orthogonal. Extend this to a maximal family $\{y_n, n \geq 1\}$ of separating vectors such that the projections $Q'_n$ onto $\{M_{y_n} : M \in M\}$ are pairwise orthogonal.

This family is countable since $\mathcal{H}$ is separable. Let $Q = (\sum Q_n)$. Then $\overline{Q} \neq I$, for otherwise Proposition 2.12 applied to $M \mid Q \mathcal{H}$ would yield a separating vector $y = Qy$, contradicting the maximality for $\{y_n\}$. Let $R = I - \overline{Q}$. Proceeding as in the previous paragraph, one shows that $R$ has uniform infinite multiplicity. Again, a contradiction has been obtained.
For $1 \leq n \leq \aleph_0$, let $M_n = M \mid P_n H$. Then $M_n$ has uniform multiplicity $n$. By Corollary 7.9 and Remark 7.11, $M_n$ is unitarily equivalent to $L^\infty(\mu_n)^{(n)}$. Furthermore, $M$ is * isomorphic to $L^\infty(\mu)$ via $\Phi(f) = f(A)$. The projections $P_n = \Phi(\chi_n)$ where $\chi_n$ are the characteristic functions pairwise disjoint measurable sets $E_n$ such that $\sum \mu(E_n) = 1$. Since $P_n$ is the identity of $M_n$, the measure $\mu_n$ is supported on $E_n$ and may be taken to be the restriction of $\mu$ to $E_n$. In particular, the $\{\mu_n\}$ are mutually singular. Putting this all together yields a unitary equivalence between $M$ and

$$L^\infty(\mu(\omega)) \bigoplus \sum_{n=1}^{\aleph_0} \bigoplus L^\infty(\mu_n)^{(n)}.$$  

Let $A$ be a self-adjoint operator. The complete unitary invariants of $A$ can be read off from Theorem 7.14. First, there is the spectrum $X = \sigma(A)$. Then there is a spectral measure $E(\cdot)$. By 7.11, there is a class $[\mu]$ of scalar measures mutually absolutely continuous to $E$. Define a multiplicity function $m(x)$ by setting $m(x) = n$ if $x$ belongs to $E_n$ where $E_n$ is the support of the multiplicity $n$ part of $\mathcal{W}(A)$. Then $m$ is defined $\mu$ almost everywhere.

### 7.15 Theorem

Two self-adjoint operators $A$ and $B$ are unitarily equivalent if and only if they have the same spectrum, scalar spectral measure, and multiplicity function.

**Proof.** If $B = UA^*U^*$, the $f(B) = Uf(A)U^*$ for every bounded Borel function $f$. Thus, by Theorem 7.14, they have the same measure class and multiplicity function. Conversely, if they have the same measure class and multiplicity function, Theorem 7.14 provides a unitary $U$ such that $f(B) = Uf(A)U^*$ for every bounded Borel function $f$. In particular, $B = UA^*U^*$.

### 7.16 Corollary

Let $\mathcal{N}$ and $\mathcal{M}$ be two nests order isomorphic to a subset $\omega$ of $[0,1]$. Let $\Phi$ and $\Psi$ be order isomorphisms of $\mathcal{N}$ and $\mathcal{M}$ onto $\omega$. Then $\psi^{-1}.\Phi$ is implemented by a unitary if and only if the two spectral measures for $\int \Phi(\mathcal{N})d\mathcal{N}$ and $\int \Psi(\mathcal{M})d\mathcal{M}$ have the same measure of class and multiplicity function.

**Proof.** Apply Theorems 7.4 and 7.15.

There is a certain difficulty with this Corollary. Namely, one must specify the order isomorphisms $\Phi$ and $\Psi$. These may not be unique. Thus to decide if $\mathcal{N}$ and $\mathcal{M}$ are unitarily equivalent, one must let $\Psi$ run over all order isomorphisms of $\mathcal{M}$ onto $\omega$ ($\Phi$ may be fixed). The problem can be
reduced to a measure theoretic problem. Consider the following special cases.

7.17 Proposition. Let $\mathcal{H}$ and $\mathcal{M}$ be two continuous, multiplicity free nests. Then $\mathcal{H}$ and $\mathcal{M}$ are unitarily equivalent.

Proof. It suffices to show that $\mathcal{M}$ (and $\mathcal{M}$) is unitarily equivalent to the Volterra nest $\mathcal{N}_t$ given by $\mathcal{N}_t = \{ f \in L^2(0,1) : \text{supp}(f) \subseteq [0,t] \}$. Let $x$ be a unit cyclic and separating vector for $\mathcal{M}$. The map $\Phi_x(M) = (Mx,x)$ carries $\mathcal{M}$ onto $[0,1]$. Let $E_{\mathcal{M}}(\cdot)$ be the spectral measure of $\mathcal{M}$, and define a scalar measure by $\mu(\cdot) = (E_{\mathcal{M}}(\cdot)x,x)$. It is clear that $\mu$ is mutually absolutely continuous with $E$. Furthermore

$$\mu(a,b) = (\Phi_x^{-1}(b) - \Phi_x^{-1}(a)x,x) = \Phi_x(\Phi_x^{-1}(b)) - \Phi_x(\Phi_x^{-1}(a)) = b - a.$$  

Hence $\mu$ equals Lebesgue measure. By Corollary 7.16, there is a unitary $U$ of $L^2(0,1)$ onto $\mathcal{H}$ such that $UN_t = \Phi_x^{-1}(t)$ for all $0 \leq t \leq 1$.

7.18 Example. It is implicit in 7.17 that $\mathcal{M}$ is parametrized by the spatially related function $\Phi_x$, not some more arbitrary indexing. Consider a nonatomic measure $\mu$ on $(0,1)$ with $\text{supp}(\mu) = [0,1]$. Define $\mathcal{M}$ in $L^2(\mu)$ by setting

$$M_t = \{ f \in L^2(\mu) : \text{supp}(f) \subseteq [0,t] \}.$$  

Then by Corollary 7.16, there is a unitary map $U$ of $L^2(\mu)$ onto $L^2(0,1)$ such that $UM_t = N_t$ for $0 \leq t \leq 1$ if and only if $\mu \sim m$ (Lebesgue measure). On the other hand, if one sets $h(t) = \mu[0,t]$, then the proof of Proposition 7.17 shows that there is always a unitary $U$ such that $UM_t = N_{h(t)}$ for $0 \leq t \leq 1$. More generally, if $h$ is an order preserving homeomorphism of $[0,1]$ onto itself, then there is a unitary operator $U$ such that $UN_t = N_{h(t)}$ if and only if the Lebesgue-Stieltjes measure $dh$ is mutually absolutely continuous with Lebesgue measure $m$.

7.19 Example. Let $\mathcal{Q}$ be the nest of Example 2.6. This is a totally atomic, multiplicity free nest. Let $\mathcal{R}$ be the nest defined on $L^2(\mu) \oplus L^2(\mathbb{R})$ by $R_t^+ = \{ f : \text{supp}(f) \subseteq (-\infty,t] \}$ and $R_t^- = \{ f : \text{supp}(f) \subseteq (-\infty,t) \}$. So $R_t^+ = Q_t^+ \oplus N_t$ where $N_t$ belongs to the canonical continuous nest on $L^2(\mathbb{R})$. The nest $\mathcal{R}$ is multiplicity free also. To see this, note that $\mathcal{R}^n$ contains projections $A_t = (Q_t^+ - Q_t^-) \oplus 0$ onto all the atoms, and hence contains $I \oplus 0$. From this, one obtains that $\mathcal{R} \cong L^\omega(\mu) \oplus L^\omega(\mathbb{R}) = L^\omega(\mu + m)$ which is multiplicity free. The map $\Phi$ taking $Q_t^+$ to $R_t^+$ is an order isomorphism of $\mathcal{Q}$ onto $\mathcal{R}$. However, no unitary operator can take $Q$ onto $\mathcal{R}$ because $\mathcal{Q}^n$ and $\mathcal{R}^n$ are not $*$-isomorphic. ($\mathcal{Q}^n$ is atomic, isomorphic to $\ell^\infty$, and $\mathcal{R}^n$ is isomorphic to $\ell^\infty \oplus L^\infty(\mathbb{R})$.) Thus Proposition 7.17 does not even extend to the general multiplicity free case.
7.20 Example. Let $C$ be the Cantor set, and let $h$ be a order preserving homeomorphism of $[0,1]$ such that $h(C)$ has positive measure. Let $C_0$ be a countable dense subset of $C$. Let $\mu$ be counting measure on $C_0$, and let $\nu$ be counting measure on $h(C_0)$. Define nests $L$ and $M$ in $L^2(\mu + m)$ and $L^2(\nu + m)$ respectively by

$$L_t^+ = \{ f \in L^2(\mu + m) : \text{supp}(f) \subseteq [0,t] \}$$

$$L_t^- = \{ f \in L^2(\mu + m) : \text{supp}(f) \subseteq [0,t] \}$$

$$M_t^+ = \{ f \in L^2(\nu + m) : \text{supp}(f) \subseteq [0,t] \}$$

$$M_t^- = \{ f \in L^2(\nu + m) : \text{supp}(f) \subseteq [0,t] \} .$$

Both $L$ and $M$ are multiplicity free nests, and $h$ is an order isomorphism of $L$ onto $M$. Furthermore, $L'' \cong \ell^\infty \oplus L^\infty(m) \cong M''$.

Suppose that there were a unitary operator $U$ taking $L$ onto $M$. Let $h'$ be the order isomorphism induced by $U$. By Corollary 7.16, $h'$ carries the measure class of $\mu + m$ onto that of $\nu + m$. Now $h'$ must take $C_0$ onto $h(C)$. Since $h'$ is continuous, $h'(C) = h(C)$. But $E_L(\cdot | C)$ is equivalent to $\mu$ which is atomic, whereas $E_M(\cdot | h(C))$ is equivalent to $\nu + m$ $|h(C)$ which has a non trivial non-atomic part. This is impossible, so $L$ and $M$ are not unitarily equivalent.

7.21. Implicit in the proof of Proposition 7.17 is the fact that when $x$ is a unit separating vector for $M''$, the map $\Phi_x(M) = (P(M)x, x)$ is an order isomorphism of $M$ which encodes the spectral measure $E_x$ via Lebesgue measure in the sense that the measure $\mu_x$ on $X = \Phi_x(M)$ given by $\mu_x(X \cap [0,t]) = t$ is mutually absolutely continuous with $E_x$. In fact, let $[0,1] \setminus X = \bigcup_{n \geq 1} (r_n - \ell_n)$ is the disjoint union of open intervals. Then

$$\mu_x(S) = m(S \cap X) + \sum_{r_n \in S} (r_n - \ell_n) . \quad (7.21.1)$$

Let the hull class of $M$ denote the set

$$h(M) = \{ \Phi_x(M) : x \text{ is a unit separating vector for } M'' \} .$$

Say that an order preserving homeomorphism is absolutely continuous if $f$ and $f^{-1}$ preserve sets of measure zero. Let the set of all such maps be denoted by $\text{AbsHom}[0,1]$.

7.22 Proposition. Let $M$ be a multiplicity free nest, and let $X = \Phi_x(M)$ for some unit separating vector $x$. Then $h(X)$ consists of $\{ f(X) : f \in \text{AbsHom}[0,1] \}$.

Proof. By Theorems 7.8 and 7.4, $M$ is unitarily equivalent to the nest on $L^2(\mu_x)$ given by the subspaces $M_t$ of functions supported in $[0,t]$ for $t$ in $[0,1]$. Under this equivalence, $x$ is taken to the constant function $1$. We
will assume that $\mathcal{M}$ is in this form.

If $f$ and $f^{-1}$ preserve sets of measure zero, then there is a strictly positive function $h$ in $L^1(0,1)$ such that

$$f(t) = \int_0^t h(s)ds .$$

Define a vector $y$ in $L^2(\mu_x)$ by

$$y(r_n) = (\int_{r_n}^{r_{n+1}} h(s)ds)^{\frac{1}{2}} , \ n \geq 1$$

$$y(t) = h(t)^{\frac{1}{2}} , \ t \in X \setminus \{r_n, n \geq 1\} .$$

Then

$$\Phi_y(M_t) = \int_{X \cap [0,t]} |y(s)|^2d\mu_x(s) = \int_0^t h(s)ds = f(t) .$$

On the other hand, let $y$ be a separating vector for $\mathcal{M}^n$ and let $f(t) = (P(M_t)y,y)$. Then $f$ carries $X$ onto $\Phi_y(M)$. Extend $f$ to a homeomorphism of $[0,1]$ by making it linear on each $[\ell_n, r_n)$. Let $C$ be a subset of $[0,1]$ with measure zero, and let $C_0 = C \cap X \setminus \{r_n, n \geq 1\}$. Then $\mu_x(C_0) = m(C \setminus X) = 0$. Thus $M_{\chi_{C_0}} = 0$ in $L^2(\mu_x)$, so

$$m(f(C_0)) = \mu_x(f(C_0)) = (M_{\chi_{C_0}}y,y) = 0 .$$

As $f$ is piecewise linear on $\bigcup[\ell_n, r_n)$, $m(f(C_0)) = 0$. So $f$ preserves sets of measure zero. Interchanging the roles of $x$ and $y$ shows that this also holds for $f^{-1}$.

7.23 Theorem. Let $\mathcal{M}$ and $\mathcal{N}$ be multiplicity free nests. Then the following are equivalent:

1) $\mathcal{N}$ is unitarily equivalent to $\mathcal{M}$.
2) $h(\mathcal{N}) = h(\mathcal{M})$.
3) $h(\mathcal{N})$ intersects $h(\mathcal{M})$.
4) Given $x$, $y$ unit separating vectors for $\mathcal{N}$ and $\mathcal{M}$, there is a function $f$ in $\text{Abs Hom}[0,1]$ such that $f(\Phi_x(\mathcal{M})) = \Phi_y(\mathcal{M})$.

Proof. Clearly, 1) implies 2) implies 3). But the first paragraph of Proposition 7.22 shows 3) implies that both $\mathcal{N}$ and $\mathcal{M}$ are unitarily equivalent to the same nest. Proposition 7.22 also shows the equivalence of 2) and 4).

This leads to a slight improvement on Corollary 7.16. Given a nest $\mathcal{N}$, let $z$ be a unit separating vector and define $\Phi_z(\mathcal{N}) = (P(N)x,x)$. Let $X = \Phi_z(\mathcal{M})$. Define a multiplicity function $m_x(t)$ on $[0,1]$ defining it to be the multiplicity function of $A = \int_X \Phi_x(\mathcal{N})dN$ for $t$ in $X$, and on each interval $(\ell_n, r_n)$ corresponding to an atom $A_n$ of $\mathcal{N}$, set $m_x(t) = -m_x((r_n)) = -\text{rank}(A_n)$. 
\textbf{7.24 Theorem.} Let \(\mathcal{N}\) and \(\mathcal{M}\) be two nests with separating vectors \(x\) and \(y\) for \(\mathcal{N}''\) and \(\mathcal{M}''\) respectively. Then \(\mathcal{N}\) and \(\mathcal{M}\) are unitarily equivalent if and only if there is an absolutely continuous order homeomorphism \(f\) of \([0,1]\) such that \(m_y(t) = m_x(f(t))\).

\textbf{Proof.} The point is simply that the measure class of \(\mathcal{N}\) on \(\Phi_2(\mathcal{N})\) and \(\Phi_2(\mathcal{M})\) are given as in (7.21.1) from Lebesgue measure on \([0,1]\). The homeomorphisms of \([0,1]\) which preserve this measure class are precisely \(\text{AbsHom}[0,1]\). The condition \(m_y = m_x \circ f\) shows that multiplicity is also preserved. Thus by Corollary 7.16, \(\mathcal{N}\) and \(\mathcal{M}\) are unitarily equivalent. The reverse implication is easy. \(\square\)

\textbf{7.25.} Why is this not the whole answer? Because given \(\mathcal{N}, x, \) and \(m_x\) and likewise \(\mathcal{M}, y\) and \(m_y\), how do you determine if an \(f\) is \(\text{AbsHom}[0,1]\) exists such that \(m_y = m_x \circ f\)? The reason it is an improvement on 7.16 is that it replaces arbitrary measure classes by the more familiar Lebesgue measure. The resulting problem remaining is strictly a measure theoretic one. Given two partitions \(\{A_n, n \in \mathbb{Z}\}\) and \(\{B_n, n \in \mathbb{Z}\}\) of \([0,1]\) into Borel sets, determine when there is an \(f\) in \(\text{AbsHom}[0,1]\) such that \(m(f(A_n)) \Delta B_n = 0\) for all \(n\).

\textbf{Notes and Remarks.}

The classification of self-adjoint operators is the classical theory of Hahn and Hellinger. The treatment used here was greatly influenced by Arveson's book on \(C^*\)-algebras [8]. The corresponding theory for nests was developed by Erdos [2]. As he wished to deal with the non-separable case, he develops the theory from the beginning. Here, we have chosen to use Theorem 7.4 instead. Proposition 7.17 is due to Kadison and Singer [1], as is Theorem 7.23. Theorem 7.24 is new.

\textbf{Exercises.}

\textbf{7.1} (Weyl-von Neumann) Show that every self-adjoint operator \(T\) on a separable Hilbert space is the sum of a diagonal operator and a compact one. Given \(\epsilon > 0\), one can choose the compact operator with norm at most \(\epsilon\).

\textbf{Hint:} Reduce to the case of a cyclic vector \(x\). Let \(E_{j,n}\) be the spectral projections for the intervals \([2^{-n}j, 2^{-n}(j+1)]\) and let \(P_n\) be the projection onto \(\text{span}\{E_{j,n}x, j \in \mathbb{Z}\}\). Show that \(\text{rank} P_n < \infty\), \(P_n\) increases strongly to \(I\), and \(\lim_{n \to \infty} \|P_n T - TP_n\| = 0\).

\textbf{7.2} (Halmos) Use the arguments of section 7.2 to show that if \(\{N_k, k \geq 1\}\) is a family of commuting normal operators, then there is a single self-adjoint operator \(T\) such that \(C^*(T)\) contains \(\{N_k, k \geq 1\}\).
(b) (Berg) Deduce that if \( \{N_k, k \geq 1\} \) is a family of commuting normal operators, then there is an atomic, maximal abelian von Neumann algebra \( D \) such that all \( N_k \) belong to \( D + K \).

(c) (Berg) In particular, if \( N \) is normal and \( \epsilon > 0 \), show that \( N = D + K \) where \( D \) is diagonal, \( K \) is compact, and \( \|K\| < \epsilon \).

(d) (Berg) Suppose \( N \) and \( M \) are normal operators such that \( \sigma(N) = \sigma_e(N) = \sigma_e(M) = \sigma(N) \). Given \( \epsilon > 0 \), show that there is a unitary \( U \) so that \( N - U M U^* \) is compact of norm at most \( \epsilon \).

(e) Two operators \( S \) and \( T \) are approximately unitarily equivalent \( (S \sim T) \) if for every \( \epsilon > 0 \), there is a unitary \( U \) such that \( \|S - U T U^*\| < \epsilon \). Show that two normal operators \( N \) and \( M \) on a separable \( \mathcal{H} \) have \( N \sim M \) if and only if \( \sigma(N) = \sigma(M) \) and the multiplicity of isolated eigenvalues are equal.

7.3 (Type I von Neumann Algebras) A von Neumann algebra \( \mathcal{M} \) is type I if every central projection dominates a non-zero projection \( P \) in \( \mathcal{M} \) such that \( P \mathcal{M} P \) is abelian (an "abelian projection"). \( \mathcal{M} \) is of type \( I_{nm} \), \( 1 \leq n, m \leq \aleph_0 \) if there is a maximal abelian von Neumann algebra \( \mathcal{M}_0 \) so that \( \mathcal{M} \) is unitarily equivalent to \( \mathcal{M}_0 \otimes \mathcal{M}_n(\mathbb{C}) \otimes \mathcal{M}_m(\mathbb{C}) \) on \( \mathcal{H} \otimes \mathbb{C}^n \otimes \mathbb{C}^m \). Show that if \( \mathcal{M} \) is type I, then there are pairwise orthogonal central projections \( E_{nm} \) with \( \sum E_{nm} = I \) such that \( \mathcal{M} |E_{nm}\mathcal{H} \) is type \( I_{nm} \).

Outline:

i) Find a maximal abelian projection \( P \). Show that the map of \( \mathcal{M}' \) to \( \mathcal{M}'_P \) is an isomorphism.

ii) Use Theorem 7.14 to decompose \( \mathcal{M}'_P \). If \( P_m \) are the projections obtained, let \( E_m \) be the minimal central projections dominating them. \( \mathcal{M}_{E_m} \cong \mathcal{H}_m \otimes \mathcal{M}_m \) where \( \mathcal{H}_m \) is abelian.

iii) Apply Theorem 7.14 to each \( \mathcal{H}_m \).

7.4* When are two nests unitarily equivalent? Or, by remark 7.25, given two partitions \( \{A_n, n \in \mathbb{Z}\} \) and \( \{B_n, n \in \mathbb{Z}\} \) of \([0,1]\) into Borel sets, determine when there is an order preserving homeomorphism \( f \) of \([0,1]\) with \( f \) and \( f^{-1} \) absolutely continuous such that \( m(f(A_n) | \Delta B_n) = 0 \) for all \( n \in \mathbb{Z} \).
8. Expectations

In this section, we consider the problem of projecting onto a von Neumann algebra, and its connection with triangular truncation.

An expectation of \( B(\mathcal{H}) \) onto a von Neumann subalgebra \( \mathcal{A} \) is a norm one projection \( \Phi \) of \( B(\mathcal{H}) \) onto \( \mathcal{A} \).

8.1 Theorem. Let \( \Phi \) be an expectation of \( B(\mathcal{H}) \) onto a von Neumann subalgebra \( \mathcal{A} \). Then

i) \( \Phi \) is self-adjoint and order preserving.

ii) \( \Phi(AXB) = A\Phi(X)B \) for all \( A, B \) in \( \mathcal{A} \) and \( X \) in \( B(\mathcal{H}) \).

iii) \( \Phi(X)^*\Phi(X) \leq \Phi(X^*X) \) for all \( X \) in \( B(\mathcal{H}) \).

Proof. Let \( X \) be a self-adjoint operator of norm one, and write \( \Phi(X) = A + iB \) where \( A \) and \( B \) are self-adjoint. Then

\[
1 + n^2 = \|X+i\|_2^2 \geq \|\Phi(X+i)\|_2^2 = \|A+i(B+nI)\|_2^2 \geq \|B+nI\|_2^2 .
\]

But the maximum of \( \|B+nI\|_2^2 \) is \( (\|B\|+|n|)^2 \geq 2|n|\|B\|+n^2 \). Thus \( \|B\| \leq \frac{1}{2}|n| \) for all \( n \), and so \( \Phi(x) \) is self-adjoint.

If \( 0 \leq X \leq I \), then \( \Phi(X) \) is self-adjoint,

\[
\|\Phi(X)\| \leq 1, \text{ and } \|I-\Phi(X)\| = \|\Phi(I-X)\| \leq 1 .
\]

Hence \( 0 \leq \Phi(X) \leq I \), and so \( \Phi \) is order preserving.

Let \( E \) be a projection in \( A \), and \( X \) be a positive operator. Since \( EXE \leq E \), \( \Phi(EXE) \leq E \). Thus

\[
\Phi(EXE) = E\Phi(EXE)E .
\]

By linearity, this holds for all operators \( X \) in \( B(\mathcal{H}) \). Next, consider an operator \( X = EXE^\perp \) of norm one. It will be shown that \( \Phi(X) = E\Phi(X)E^\perp \). Decompose \( \mathcal{H} \) as \( E\mathcal{H} \oplus E^\perp \mathcal{H} \). Then \( X \) has a matrix form \( \begin{bmatrix} 0 & Y \\ 0 & 0 \end{bmatrix} \) and \( \Phi(X) \) has the form \( (A_{ij}) \). Then if \( \lambda \) is any scalar

\[
(1+|\lambda|^2)^* = \begin{bmatrix} \lambda & Y \\ 0 & 0 \end{bmatrix} = \|\lambda E + X\| \geq \|\Phi(\lambda E + X)\|
\]

\[
\geq \|E\Phi(\lambda E + X)E\| = \|\lambda I + A_{11}\| \geq \|\lambda I + ReA_{11}\| .
\]
However, max\( \| n I + Re A_{11} \| = n + \| Re A_{11} \| > (1+n^2)^{1/4} \) for large \( n \) unless \( Re A_{11} = 0 \). Likewise, one obtains \( Im A_{11} = 0 \) so \( A_{11} = 0 \), and consideration of \( \| \lambda E^\perp + X \| \) yields \( A_{22} = 0 \). Finally, \( A = E^\perp \Phi(X)E = \begin{bmatrix} 0 & 0 \\ A_{21} & 0 \end{bmatrix} \) belongs to \( \mathcal{A} \), so

\[
\begin{align*}
\max(\| X \|, n \| A_{21} \|) &= \| \begin{bmatrix} 0 & Y \\ n A_{21} & 0 \end{bmatrix} \| = \| n A + X \| \\
&\geq \| \Phi(n A + X) \| = \| n A + \Phi(X) \| \\
&\geq \| E^\perp(n A + \Phi(X))E \| = (n+1)\| A \|.
\end{align*}
\]

By letting \( n \) tend to infinity, one obtains \( A_{21} = 0 \).

It follows that

\[
\Phi(EX) = \Phi(EXE) + \Phi(EXE^\perp) = E\Phi(EXE) + E\Phi(EXE^\perp) = E\Phi(EX).
\]

Since one therefore has \( \Phi(E^\perp X) = E^\perp \Phi(E^\perp X) \) also, one obtains

\[
E\Phi(X) = E\Phi(EX) + E\Phi(E^\perp X) = E\Phi(EX) = \Phi(EX).
\]

By the spectral theorem, every operator in \( \mathcal{A} \) is the norm limit of a linear combination of projections in \( \mathcal{A} \). Thus by the continuity of \( \Phi \), one obtains \( \Phi(A X) = A \Phi(X) \) for all \( A \) in \( \mathcal{A} \) and \( X \) in \( B(\mathcal{H}) \). Taking adjoints yields \( \Phi(XA) = \Phi(X)A \) as well. This proves (ii).

Let \( X \) belong to \( B(\mathcal{H}) \). By (i) and (ii),

\[
0 \leq \Phi((X - \Phi(X))(X - \Phi(X))) \\
= \Phi(X^*X - X^*\Phi(X) - \Phi(X)^*X + \Phi(X)^*\Phi(X)) \\
= \Phi(X^*X) - \Phi(X^*)\Phi(X).
\]

\[\blacksquare\]

8.2. A von Neumann algebra is called \emph{approximately finite} (AF) if it is the weak operator closure of the union of an increasing net of finite dimensional \( C^* \) subalgebras. For separately acting algebras, a sequence will suffice.

Consider a finite dimensional von Neumann algebra \( \mathcal{A} \). We wish to "average" over the unitary group \( U(\mathcal{A}) \). As this group is compact, it has a Haar measure and integrating with respect to this measure will work nicely. However, a somewhat more elementary approach will be used here. By the Wedderburn Theorem for finite dimensional semi-simple rings, one knows that \( \mathcal{A} \) is isomorphic to a direct sum of full matrix algebras \( M_n(\mathbb{C}) \). The unitary group \( U_n \) of \( M_n \) contains a finite subgroup \( G_n \) such that \( G'_n = \mathbb{C}I \). For example, choose a basis \( \{ e_1, ..., e_n \} \). Let \( \mathcal{V}_n \) denote the group of diagonal symmetries with respect to this basis. (This is the group
of diagonal matrices with diagonal entries equal to ±1). And let $S_n$ denote the group of permutation matrices given by $U_{e^j} = e^{\pi(i)}$ for each permutation $\sigma$. Then $U_{e^j}V_nU_{e^j}^* = V_n$. Thus the group $G_n$ generated by $V_n$ and $S_n$ is finite of order $2^n n!$. If $T$ belongs to $M_n$ and commutes with $V_n$, then $T$ is diagonal. So if $T$ also commutes with $S_n$, it must be scalar. Thus $G_n' = CI$.

Now if $A$ is isomorphic to $\bigoplus_{j=1}^k M_{n_j}$, there is a finite subgroup $G$ of $U(A)$ isomorphic to $G_{n_1} \times G_{n_2} \times \cdots \times G_{n_k}$ such that $G' = U(A)' = A'$. One may average an operator $T$ over $G$ by setting

$$m_G(T) = \frac{1}{|G|} \sum_{U \in G} UTU^* .$$

### 8.3 Theorem

Let $A$ be a von Neumann algebra with AF commutant. Then there is an expectation $\Phi$ of $B(H)$ onto $A$ such that for every $X$ in $B(H)$, $\Phi(X)$ belongs to the weak* closed convex hull of $\{UXU^* : U \in U(A)\}$.

**Proof.** First suppose $A'$ is finite dimensional, and let $G$ be a finite unitary group in $A'$ such that $G' = A$. Define $\Phi(X) = m_G(X)$. Then if $V$ belongs to $G$,

$$V\Phi(X) = \frac{1}{|G|} \sum_{U \in G} VUXU^* = \frac{1}{|G|} \sum_{U \in G} (UXU^*)XV = \Phi(X)V .$$

Thus $\Phi(X)$ belongs to $G'$ = $A$. It is clearly in the convex hull of $\{UXU^* : U \in A'\}$, and thus $\Phi$ is contractive. For any $X$ in $A$, $UXU^* = X$ for all $U$ in $G$, and hence $\Phi(X) = X$. So $\Phi$ is an expectation.

Now, let $A'$ be the weak closure of the union of an increasing sequence $A_n$ of finite dimensional subalgebras. Let $\Phi_n$ be the expectation onto $A_n'$ constructed above. Think of $\Phi_n$ as elements of $L(B(H))$, the space of bounded linear maps of $B(H)$ into itself. Consider the point-weak operator topology on this space. This is the topology obtained from thinking of $L(B(H))$ as a subset of

$$\prod_{T \in B(H), \text{WOT}} (B(H), \text{WOT})$$

where the embedding is given by sending $\Phi$ to $\{\Phi(T), T \in B(H)\}$. The unit ball of $B(H)$ is compact in the weak operator topology (WOT). And thus
the set \( \prod_{T \in \mathcal{B}(\mathcal{H})} \{ X \in \mathcal{B}(\mathcal{H}) : \|X\| \leq \|T\| \} \) is compact by Tychonoff's Theorem. So the unit ball of \( L(\mathcal{B}(\mathcal{H})) \) is compact in the point-weak operator topology.

The sequence \( \Phi_n \) is bounded, so it has a cluster point \( \Phi \) in the point-weak operator topology. For any \( X \in \mathcal{B}(\mathcal{H}) \), \( \Phi_n(X) \) belongs to \( \mathcal{A}_k' \) for all \( n \geq k \). Thus \( \Phi(X) \) belongs to \( \mathcal{A}_k' \) for all \( k \), and hence belongs to their intersection \( \mathcal{A} \). In particular, if \( X \) belongs to \( \mathcal{A} \), \( \Phi_n(X) = X \) for all \( n \). So \( \Phi \) is an expectation onto \( \mathcal{A} \). Each \( \Phi_n(X) \) belongs to the convex hull of \( \{ UU^* U \in \mathcal{U}(\mathcal{A}') \} \). Thus \( \Phi(X) \) belongs to the weak operator closure.

8.4 Lemma. Every von Neumann algebra \( \mathcal{A} \) such that \( \mathcal{A} \) or \( \mathcal{A}' \) is abelian is AF.

Proof. Let \( \mathcal{A} \) be abelian. Associate to each partition \( \mathcal{E} = \{ E_1, \ldots, E_n \} \) of the identity into the sum of projections \( E_j \) in \( \mathcal{A} \), the subalgebra \( \mathcal{E} \). This is a net of finite subalgebras, ordered by inclusion whose union is dense in \( \mathcal{A} \). So \( \mathcal{A} \) is AF. If \( \mathcal{A} \) acts on a separable Hilbert space, choose a countable sequence \( \{ E_j, j \geq 1 \} \) of projections such that \( \text{span} \{ E_j, j \geq 1 \} \) is weakly dense in \( \mathcal{A} \). Then \( \mathcal{A}_n = \text{span} \{ E_1, \ldots, E_n \} \) is an increasing sequence with the desired properties.

If \( \mathcal{A}' \) is abelian, then by Theorem 6.14, there are central projections \( E_1, E_2, E_3, \ldots \) summing strongly to the identity such that \( \mathcal{A}' | E_n \mathcal{H} \) has multiplicity \( n \). Thus there is a maximal abelian algebra \( L^\infty(\mu_n) \) such that \( \mathcal{A} | E_n \mathcal{H} \) is isomorphic to \( M_n \otimes L^\infty(\mu_n) \) (or \( \mathcal{B}(\mathcal{H}) \otimes L^\infty(\mu_n) \) if \( n = \infty \)). Since \( L^\infty(\mu_n) \) is AF by the first paragraph, \( M_n \otimes L^\infty(\mu_n) \) is AF. And since \( \mathcal{B}(\mathcal{H}) \) is also AF, this holds for \( n = \infty \) as well. Putting it all together shows that \( \mathcal{A} \) is AF. (See Exercises.)

8.5 Corollary. If \( \mathcal{N} \) is a nest, there are expectations onto \( \mathcal{N}' \) and \( \mathcal{N}'' \).

One can ask when the expectation onto \( \mathcal{A} \) is unique. An expectation is called faithful if \( \Phi(X) = 0 \) when \( X = 0 \). The expectation is called normal if \( \Phi \) is weak\(^*\) continuous. Even faithful, normal expectations need not be unique. For example, let \( \mathcal{A} \) be the algebra of all scalars in \( M_n(\mathbb{C}) \). An expectation has the form \( \Phi(X) = \tau(X)I \) where \( \tau \) is a norm one linear functional on \( M_n(\mathbb{C}) \) such that \( \tau(I) = 1 \). Thus \( \tau(X) = tr(XT) \) where \( ||T||_1 = 1 = trT \). This implies that \( T \) is positive. The expectation \( \Phi \) is faithful if and only if \( T \) has rank \( n \). For example, \( T = I \) yields \( \Phi_e(X) = tr(X)I \) which is "canonical". But there are many others, all of which are automatically normal. For example, on \( M_2 \), define \( \Phi(X) = \left( \frac{3}{4} x_{11} + \frac{1}{4} x_{22} \right) I \).
8.6 Theorem. Let $\mathcal{A}$ be a von Neumann algebra with abelian commutant. If $\mathcal{A}'$ is atomic, then there is a unique expectation onto $\mathcal{A}$, and it is faithful and normal. If $\mathcal{A}'$ is not atomic, then there is no faithful or normal expectation onto $\mathcal{A}$, and the expectation is not unique.

Proof. If $\mathcal{A}'$ is atomic, it contains minimal projections $\{E_n, n \geq 1\}$ and $\sum_{n \geq 1} E_n = I$. Thus if $X$ belongs to $\mathcal{B}(\mathcal{H})$, $E_n X E_n$ belong to $\mathcal{A}$ for all $n \geq 1$. Hence if $\Phi$ is any expectation onto $\mathcal{A}$,

$$\Phi(X) = \sum_{n \geq 1} \Phi(X) E_n = \sum_{n \geq 1} E_n \Phi(X) E_n$$

$$= \sum_{n \geq 1} \Phi(E_n X E_n) = \sum_{n \geq 1} E_n X E_n = \Delta(X).$$

Thus the only expectation is the "compression to the diagonal", which is easily shown to be faithful and normal. (See Proposition 4.4.)

If $\mathcal{A}'$ is not atomic, then $\mathcal{A}'$ contains a projection $E$ such that $\mathcal{A}' | E \mathcal{H}$ is isomorphic to $L^\infty(0,1)$. (This is a classical theorem of measure theory that every finite nonatomic Borel measure is equivalent to Lebesgue measure (c.f. Royden [1], section 15.2). This fact is implicit in the proof of Proposition 7.17.) It follows as in Lemma 3.5 that if $K$ is any compact operator in $\mathcal{B}(E \mathcal{H})$, and $\epsilon > 0$ is given, then there are projections $E_1, \ldots, E_n$ in $\mathcal{A}'$ such that $E = \sum_{i=1}^n E_i$ and $\|E_i K E_i\| < \epsilon$. Hence for any expectation $\Phi$,

$$\Phi(K) = \sum_{i=1}^n \Phi(K) E_i = \sum_{i=1}^n E_i \Phi(K) E_i = \Phi(\sum_{i=1}^n E_i K E_i).$$

Thus $\|\Phi(K)\| < \epsilon$ for all $\epsilon > 0$, and so $\Phi(K) = 0$. Therefore $\Phi$ is not faithful. As the compact operators on $E \mathcal{H}$ are weak* dense in $\mathcal{B}(E \mathcal{H})$, $\Phi$ is not normal either.

The non-uniqueness in general follows easily from the non-uniqueness in the multiplicity one case. This will follow from Corollary 8.10 below.

An invariant mean for a semigroup $G$ is a state $m$ on the von Neumann algebra $\ell^\infty(G)$ such that $m(F) = m(gF)$ when $gF(g') = F(gg')$ for all $g$ in $G$ and $F$ in $\ell^\infty(G)$. A semigroup which has an invariant mean is called amenable.

8.7 Theorem. Let $G$ be an abelian semigroup. Then there is an invariant mean on $G$. 

Proof. Let $\mathcal{M}$ be the subspace spanned by $\{F - gF: g \in G, F \in \ell^{\infty}(G)\}$. It will be shown that $\text{det}(1, \mathcal{M}) = 1$ where $1(g) = 1$ for all $g$. Let $H = \sum_{i=1}^{n} F_i - g_i F_i$ be an element of $\mathcal{M}$. Average over the set $S = \{\prod_{j=1}^{k} g_j^{i_j}: 0 \leq k_j < p\}$. Let $S_i$ be the subset of $S$ such that $k_i = 0$,

$$\frac{1}{p^n} \sum_{s \in S} gH = \sum_{i=1}^{n} \frac{1}{p^n} \sum_{s \in S_i} \sum_{i=0}^{k-1} g_i^{k-1} F_i - g_i^{k+1} F_i$$

$$= \sum_{i=1}^{n} \frac{1}{p^n} \sum_{s \in S_i}^{k=0} \sum_{i=1}^{n} \frac{1}{p} (F_i - g_i F_i) .$$

Hence

$$\|\frac{1}{p^n} \sum_{s \in S} gH\| \leq \frac{2}{p n} \sum_{i=1}^{n} \|F_i\|_{\infty} .$$

However, $g1 = 1$ for all $g$, so

$$\|1 - H\| = \frac{1}{p^n} \sum_{s \in S} \|1 - gH\| \geq \|1 - \frac{1}{p^n} \sum_{s \in S} gH\| \geq 1 - \frac{2}{p} \sum_{i=1}^{n} \|F_i\|_{\infty} .$$

Letting $p$ tend to $\infty$ yields $\|1 - H\| \geq 1$.

By the Hahn-Banach Theorem, there is a norm one linear functional $m$ on $\ell^{\infty}(G)$ such that $m(1) = 1$ and $m$ annihilates $\mathcal{M}$. Thus $m$ is a positive linear functional, and

$$0 = m(F - gF) = m(F) - m(gF)$$

for all $F$ in $\ell^{\infty}(G)$. So $m$ is an invariant mean. \(\blacksquare\)

This yields another proof of:

8.8 Corollary. If $\mathcal{A}$ is a von Neumann algebra with abelian commutant, then there is an expectation $\Phi$ of $\mathcal{B}(\mathcal{H})$ onto $\mathcal{A}$ such that $\Phi(X)$ belongs to the weak* closed convex hull of $\{UXU^*: U \in \mathcal{U}(\mathcal{A}').\}$

Proof. Let $m$ be an invariant mean on $\mathcal{U}(\mathcal{A}')$. For $X$ in $\mathcal{B}(\mathcal{H})$ and $T$ in $C_1$, define $F_{X,T}(U) = tr(UXU^*T)$. Define a linear functional on $C_1$ by $\Phi(T) = m(F_{X,T})$. Since $C_1' = B(\mathcal{H})$ by Theorem 1.15, this determines a unique operator $\Phi(X)$ such that $\Phi(T) = tr(\Phi(X)T)$. For $V$ in $\mathcal{U}(\mathcal{A}')$,

$$F_{X,TV}(U) = tr(UXU^*TV) = tr(VUXU^*T)$$

$$= tr((VU)X(VU)^*TV) = F_{X,TV}(VU) = \nu F_{X,TV}(U) .$$

Hence
\[ \text{tr}(V\Phi(X)T) = \text{tr}(\Phi(X)TV) = m(FX_V T) \\
= m(VFX_V T) = m(FX_V T) \\
= \text{tr}(\Phi(X)VT). \]

This holds for every \( T \) in \( C_1 \). Hence \( V\Phi(X) = \Phi(X)V \). Thus \( \Phi(X) \) belongs to \( \mathcal{U}(\mathcal{A}^\prime) = \mathcal{A} \).

If \( \Phi(X) \) were not in the weak* closed convex hull of \( \{UXU^* : U \in \mathcal{U}(\mathcal{A}^\prime)\} \), then the Hahn-Banach Theorem provides a weak* continuous linear functional that separates them. Namely, there is a trace class operator \( T \) so that

\[ \text{Re} \ m(FX,T) = \text{Re} \ \text{tr}(\Phi(X)T) > \sup_{\mathcal{U}} \text{Re} \ \text{tr}(UXU^*) = \|\text{Re} \ F_X T\|_\infty. \]

This is absurd since \( m \) is norm one. \( \blacksquare \)

Let \( \mathcal{H} \) be \( L^2(\mathcal{T},m) \) where \( \mathcal{T} \) is the unit circle and \( m \) is normalized Lebesgue measure. The algebra \( L^\infty = L^\infty(\mathcal{T},m) \) acts on \( L^2 \) by multiplication: \( M_f h = fh \). This is a maximal abelian von Neumann algebra. Let \( e_n(z) = z^n \) for \( n \) in \( \mathbb{Z} \) be the standard orthonormal basis for \( \mathcal{H} \). Let \( P_n \) be the projection onto \( \text{span}\{e_k : k \geq n\} \); and let \( \mathcal{P} \) be the nest \( \{\{0\},\mathbb{N},P_n \mathbb{N},n \in \mathbb{Z}\} \). \( H^\infty \) is the subalgebra of \( L^\infty \) consisting of those functions \( h \) with analytic Fourier series \( h \sim \sum_{n \geq 0} a_n e^n \).

**8.9 Theorem.** There is an expectation \( \Phi \) of \( \mathcal{B}(L^2(\mathcal{T})) \) onto \( L^\infty \) such that \( \Phi(P_n) = I \) for all \( n \in \mathbb{Z} \), and \( \Phi \) takes \( \mathcal{T}(\mathcal{P}) \) onto \( \{M_h : h \in H^\infty\} \).

**Proof.** Consider the semigroup of unitaries \( \mathcal{S} = \{M_{z^n} : n \geq 0\} \). Let \( m \) be an invariant mean on \( \mathcal{S} \), and repeat the proof of Corollary 8.8. Since \( \mathcal{S}^\prime = L^\infty \), one obtains an expectation \( \Phi \) onto \( L^\infty \). Furthermore,

\[ (\Phi(P_m e_k, e_k) = \text{tr}(\Phi(P_m e_k \otimes e_k^*) \\
= m(\text{tr} M_{z^n} P_m M_{z^n} e_k \otimes e_k^*) = m((P_m e_{k+n}, e_{k+n}^*)) = 1 \]

since \( (P_m e_{k+n}, e_{k+n}^*) = 1 \) for \( n \) sufficiently large. Hence \( \Phi(P_m) = I \). Finally, if \( X \) belongs to \( \mathcal{T}(\mathcal{P}) \), then for \( k < \ell \) one has \( (X e_k, e_\ell) = 0 \). By a similar computation to the one above,

\[ (\Phi(X) e_k, e_\ell) = m((X e_{k+n}, e_{\ell+n})) = 0 \]

Now \( \Phi(X) = M_h \) and \( h = \Phi(X)e_0 \) belongs to \( \text{span}\{e_k : k \geq 0\} \). Hence \( h \) belongs to \( H^\infty \). \( \blacksquare \)
8.10 Corollary. The expectation onto $L^\infty(T)$ is not unique.

Proof. In place of the semigroup $S$, use $S^*$. This yields another expectation $\Psi$. But a reworking of the previous proof yields $\Psi(P_n) = 0$ for all $n$. So $\Psi \neq \Phi$.

Now we return to the problem considered in Chapter 4 of the convergence of triangular integrals.

8.11 Theorem. Let $\mathcal{N}$ be a nest, and let $\{\mathcal{F}\}$ be the finite subnets of $\mathcal{N}$ ordered by inclusion. Then $\lim_\mathcal{F} D_\mathcal{F}(X)$ converges in norm if and only if $X$ belongs to the closure of

$$D(\mathcal{N}) + \text{rad } T(\mathcal{N}) + \text{rad } T(\mathcal{N})^*.$$

In this case, the limit $D_\mathcal{N}(X)$ agrees with $\Phi(X)$ for every expectation onto $D(\mathcal{N})$.

Proof. Suppose $X = D + R + S^*$ where $D$ commutes with $\mathcal{N}$ and $R$ and $S$ belong to the radical of $T(\mathcal{N})$. For every $\epsilon > 0$, there is by Theorem 6.7 a finite subnest $\mathcal{F}$ such that $||\Delta_{\mathcal{F}}(R)|| + ||\Delta_{\mathcal{F}}(S)|| < \epsilon$. So

$$\Delta_{\mathcal{F}}(X) = D + \Delta_{\mathcal{F}}(R) + \Delta_{\mathcal{F}}(S)^*$$

converges to $D$. If $\Phi$ is any expectation, and $E_i$ are the intervals of $\mathcal{F}$,

$$\Phi(R) = \sum \Phi(R) E_i = \sum E_i \Phi(R) E_i = \Phi(\sum E_i RE_i).$$

Thus $\Phi(R) = 0 = \Phi(S^*)$. So $\Phi(X) = D_\mathcal{N}(X)$. As $D_\mathcal{F}$ and $\Phi$ are continuous, these statements extend to the norm closure.

On the other hand, if $\lim_\mathcal{F} D_\mathcal{F}(X)$ exists, let $D$ be this limit. For every $\epsilon > 0$, there is a finite subnest $\mathcal{F}$ such that $||\Delta_{\mathcal{F}}(X - D)|| < \epsilon$. Then

$$X - \Delta_{\mathcal{F}}(X - D) = D + L_{\mathcal{F}}(X) + L_{\mathcal{F}}(X^*)^*.$$

The operator $L_{\mathcal{F}}(X)$ belongs to $\text{rad } T(\mathcal{N})$ and $L_{\mathcal{F}}(X^*)^*$ belongs to $\text{rad } T(\mathcal{N})^*$. So $X$ belongs to the closure of $D(\mathcal{N}) + \text{rad } T(\mathcal{N}) + \text{rad } T(\mathcal{N})^*$.

8.12 Theorem. Let $\mathcal{N}$ be a nest. Then $\mathcal{U}_\mathcal{N}(X) = \lim_\mathcal{F} U_{\mathcal{F}}(X)$ exists if and only if $X$ belongs to $T(\mathcal{N}) + \text{rad } T(\mathcal{N})^*$. Likewise, $L_{\mathcal{N}}(X)$ exists if and only if $X$ belongs to $T(\mathcal{N})^* + \text{rad } T(\mathcal{N})$. Any two of $U_{\mathcal{N}}(X)$, $L_{\mathcal{N}}(X)$ and $D_{\mathcal{N}}(X)$ exist if and only if all three exist if and only if $X$ belongs to $D(\mathcal{N}) + \text{rad } T(\mathcal{N}) + \text{rad } T(\mathcal{N})^*$.

Proof. First we remark that the closures of these sets are not used because truncation is not continuous. Let $X = T + R^*$ where $T$ belongs to $T(\mathcal{N})$ and $R$ belongs to $\text{rad } T(\mathcal{N})$. Then for $\epsilon > 0$, there is a finite nest $\mathcal{F}$ so that $||\Delta_{\mathcal{F}}(R)|| < \epsilon$ by the Ringrose condition (Theorem 6.7). Hence
\[ U_T(X) = T + U_T(R^*) = T + \Delta_T(R)^* \]
converges to \( T \). On the other hand, if \( T = \lim T(U_T(X)) \), then
\[ R = X - T = \lim X - U_T(X) = \lim L_{-T}(X). \]

Each \( L_{-T}(T) \) belongs to \( \text{rad} \ T(\mathcal{N})^* \), which is closed. So \( R \) belongs to \( \text{rad} \ T(\mathcal{N})^* \).

Now as \( L_{-X}(X) = X - U_{-X}(X) \), the lower truncation result is immediate. Also \( D_T(X) = U_T(X) - L_T(X) \), so if two limits exist, so does the third. If \( X \) belongs to \( D(\mathcal{N}) + \text{rad} \ T(\mathcal{N}) + \text{rad} \ T(\mathcal{N})^* \), all the limits exist as above. Conversely, if all the integrals converge, then
\[ X = D_T(X) + L_T(X) + L_{-X}(X) \]
is written as a sum in \( D(\mathcal{N}) + \text{rad} \ T(\mathcal{N}) + \text{rad} \ T(\mathcal{N})^* \).

Let \( \mathcal{N} \) be a nest. A partition is a possibly infinite collection \( \mathcal{E} \) of intervals \( E_\alpha = P(N_\alpha) - P(M_\alpha) \) for \( M_\alpha < N_\alpha \) in \( \mathcal{N} \) such that \( \sum E_\alpha = I \).

Define a homomorphism of \( T(\mathcal{N}) \) into itself by \( \Delta_\mathcal{E}(T) = \sum E_\alpha TE_\alpha \).

Larson's \( \mathcal{R}(\mathcal{N}) \) ideal is the set of operators \( T \) in \( T(\mathcal{N}) \) such that for every \( \epsilon > 0 \), there is a partition \( \mathcal{E} \) such that \( \| \Delta_\mathcal{E}(T) \| < \epsilon \). This is a generalized Ringrose condition. If \( \mathcal{N} \) is atomic, one may take the maximal partition \( \{A_\alpha\} \) of atoms of \( \mathcal{N} \). In this case, \( \mathcal{R}(\mathcal{N}) \) is the strictly upper triangular operators, which coincides with the kernel of the diagonal map.

**8.13 Proposition.** \( \mathcal{R}(\mathcal{N}) \) is a closed, two sided ideal of \( T(\mathcal{N}) \). The net \( D_T(T) \) converges strongly to 0 for every \( T \) in \( \mathcal{R}(\mathcal{N}) \), and \( \Phi(T) = 0 \) for every expectation onto the diagonal. The set \( D(\mathcal{N}) + \mathcal{R}(\mathcal{N}) \) is a norm closed subalgebra of \( T(\mathcal{N}) \) on which \( D(\mathcal{N})(\cdot) \) exists, and agrees with every expectation onto \( D(\mathcal{N}) \).

**Proof.** Let \( R \) belong to \( \mathcal{R}(\mathcal{N}) \) and let \( T \) belong to \( T(\mathcal{N}) \). Then \( \Delta_\mathcal{E}(RT) = \Delta_\mathcal{E}(R)\Delta_\mathcal{E}(T) \) and \( \Delta_\mathcal{E}(TR) = \Delta_\mathcal{E}(T)\Delta_\mathcal{E}(R) \). Thus it is immediate that \( \mathcal{R}(\mathcal{N}) \) is a 2-sided ideal. Since each \( \Delta_\mathcal{E} \) is contractive, it is easy to verify that \( \mathcal{R}(\mathcal{N}) \) is closed. Let \( x \) be a vector, and let \( \epsilon \geq 0 \) be given. Choose \( \mathcal{E} \) so that \( \| \Delta_\mathcal{E}(R) \| < \epsilon \). There is a finite subset \( E_1, \ldots, E_n \) of \( \mathcal{E} \) such that \( \| \left( \sum_{i=1}^n E_i \right) x \| < \epsilon \). Let \( \mathcal{T} \) be any finite subnest of \( \mathcal{N} \) containing the end points of \( E_1, \ldots, E_n \). Then
\[ \| D_f(R)x \| = \| D_f(\sum_{i=1}^{n} E_i RE_i + (\sum_{i=1}^{n} E_i^{-1} R (\sum_{i=1}^{n} E_i)^{-1}))x \| \]
\[ \leq \| \sum_{i=1}^{n} E_i RE_i \| \| x \| + \| D_f((\sum_{i=1}^{n} E_i^{-1} R (\sum_{i=1}^{n} E_i)^{-1})) \| \| (\sum_{i=1}^{n} E_i)^{-1}x \| \]
\[ < \epsilon (\| x \| + \| R \|) \cdot \]

Thus \( D_f(R) \) converges strongly to 0. (Note that \( D_f(R)^*x \) tends to zero also.)

Next, if \( \Phi \) is any expectation onto \( D(\mathcal{N}) \), then
\[ \Phi(R) = \sum \Phi(R)E_\alpha = \sum E_\alpha \Phi(R)E_\alpha = \Phi(\sum E_\alpha RE_\alpha) \cdot \]

As the right hand side can be made arbitrarily small, \( \Phi(R) = 0 \). The last sentence of the theorem is trivial except for the closure of \( D(\mathcal{N}) + \mathcal{R}_\infty(\mathcal{N}) \).
If \( T_n = D_n + R_n \) converges to \( T \), then
\[ \| D_n - D_m \| = \| \Phi(T_n - T_m) \| \leq \| T_n - T_m \| \]
for any expectation \( \Phi \). Thus \( D_n \) converges to some \( D \) in \( D(\mathcal{N}) \). Whence \( R_n \) converges to \( T - D \). Since \( \mathcal{R}_\infty \) is closed, \( T - D \) belongs to \( \mathcal{R}_\infty \) as desired.

\textbf{Notes and Remarks.}

Theorem 8.1 is due to Tomiyama [1]. Schwartz [1] introduced property \( P \) for a von Neumann algebra. A von Neumann algebra \( \mathcal{A} \) has this property if the weak closed convex hull of \( \{ UXU^* : U \in U(\mathcal{A}') \} \) always intersects \( \mathcal{A} \) for each \( X \) in \( B(\mathcal{H}) \). Theorem 8.3 is essentially due to Schwartz, and shows that AF implies property \( P \). This in turn implies that there is an expectation of \( B(\mathcal{H}) \) onto \( \mathcal{A} \). Such algebras are called injective since they are precisely the von Neumann algebras such that every completely positive map \( \phi \) of a von Neumann algebra \( B_0 \subset B \) into \( \mathcal{A} \) extends to a completely positive map of \( B \) into \( \mathcal{A} \). This follows from a theorem of Arveson [4] (see Theorem 20.10) which shows that \( B(\mathcal{H}) \) is injective followed by the expectation onto \( \mathcal{A} \). The big theorem in this connection is a combination of work due to Connes [1], Choi and Effros [1,2], and Effros and Lance [1].

\textbf{Theorem.} Let \( \mathcal{A} \) be a von Neumann algebra. Then the following are equivalent.

(i) \( \mathcal{A} \) is AF.
(ii) \( \mathcal{A} \) has property \( P \).
(iii) \( \mathcal{A} \) is injective.
(iv) \( \mathcal{A} \) is semidiscrete.

A von Neumann algebra is \textit{semidiscrete} if there is a nest of finite rank, completely positive, weak* continuous contractions of \( \mathcal{A} \) into itself converging pointwise to the identity map in the weak* topology. In
particular, every type I von Neumann algebra is injective (see Exercises) and \( \mathcal{A} \) is AF if and only if \( \mathcal{A}' \) is AF.

Theorem 8.6 is due to Arveson [2] and Theorem 8.9 and Corollary 8.10 are also due to Arveson [7]. Theorems 8.11 and 8.12 are due to Erdos and Longstaff [1]. Proposition 8.13 is due to Larson [4].

Exercises.

8.1 (a) Show that the von Neumann algebra direct sum of AF algebras is AF.

(b) If \( \mathcal{A} \) and \( \mathcal{B} \) are von Neumann algebras on \( \mathcal{H} \) and \( \mathcal{K} \) respectively, let \( \mathcal{A} \otimes \mathcal{B} \) denote the weakly closed subalgebra of \( B(\mathcal{H} \otimes \mathcal{K}) \) generated by \( \{A \otimes B : A \in \mathcal{A}, B \in \mathcal{B}\} \). Show that if \( \mathcal{A} \) and \( \mathcal{B} \) are AF, then so is \( \mathcal{A} \otimes \mathcal{B} \).

8.2 Use Exercise 7.3 to prove that type I von Neumann algebras are AF.

8.3 Generalize the Hahn-Banach Theorem to maps into \( L^\infty(\mu) \) as follows:

(i) Show that the real valued functions \( L^\infty(\mu) \) is a complete lattice under ess.sup and ess.inf.

(ii) Let \( \Phi \) be a norm one linear map of a real Banach space \( X \) into \( L^\infty(\mu) \). Let \( X \) be a subspace of \( Y \), and let \( y \) belong to \( Y \). In order to extend \( \Phi \) to a contraction of \( \text{span}(X,y) \) into \( L^\infty(\mu) \) it suffices to find an \( f_0 \) in \( L^\infty(\mu) \) such that

\[
\text{ess.sup}_{x \in X} \|x+y\|\Phi(x) \leq f_0 \leq \text{ess.inf}_{x \in X} \|x+y\|\Phi(x).
\]

(iii) Show that this is always possible. Then use Zorn's lemma.

(iv) Complexify.

(v) Obtain an expectation onto any abelian von Neumann algebra.

8.4 Let \( \mathcal{N} \) be a nest, and \( \{F\} \) its net of finite subnets. Let

\[
\mathcal{J}(\mathcal{N}) = \{T \in \mathcal{T}(\mathcal{N}) : D_T(T) \text{ converges strongly to zero} \}.
\]

(a) Show that \( \mathcal{J}(\mathcal{N}) \) is a closed two sided ideal of \( \mathcal{T}(\mathcal{N}) \) containing \( \mathcal{K}^\infty(\mathcal{N}) \).

(b)* Characterize \( \mathcal{J}(\mathcal{N}) \).
9. Distance Formulae

In this section, two important estimates for the distance to von Neumann algebras and nest algebras are obtained. These results are crucial to later developments. A number of related estimates will be developed as well.

9.1 Lemma. Let $A$, $B$, and $C$ be operators in $B(\mathcal{H}_1)$, $B(\mathcal{H}_2,\mathcal{H}_1)$, and $B(\mathcal{H}_1,\mathcal{H}_2)$ respectively. Then there is an operator $X_0$ in $B(\mathcal{H}_2)$ such that

$$\| A \begin{bmatrix} B & X_0 \end{bmatrix} \| = \inf_X \| A \begin{bmatrix} B & X \end{bmatrix} \| = \max \{ \| [A \ B] \|, \| A \end{bmatrix} \| \} .$$

If $A$ is compact, then $X_0$ may be taken to be compact.

Proof. If $A = 0$, take $X_0 = 0$. Otherwise, scale the operators $A, B, C$ so that $\max \{ \| [A \ B] \|, \| A \end{bmatrix} \| \} = 1$. Then

$$I \geq \begin{bmatrix} A^* & A \end{bmatrix} = A^*A + CC^* \ .$$

So $C^*C \leq I - A^*A$. Hence for any vector $x$,

$$\| Cx \|^2 = (C^*Cx,x) \leq (1 - A^*Ax,x) = \|(1 - A^*A)^{1/2}x \|^2 .$$

Thus one may define an operator $L$ in $B(\mathcal{H}_1,\mathcal{H}_2)$ by

$$L(1 - A^*A)^{1/2}x = Cx$$

for vectors in the range of $(1 - A^*A)^{1/2}$, and $Ly = 0$ if $y$ is orthogonal to this range. The inequality shows that $\| L \| \leq 1$, and hence $L$ extends by continuity to all of $\mathcal{H}_1$. So $C = L(1 - A^*A)^{1/2}$. Similarly, one obtains $B^* \leq 1 - AA^*$, and hence $B^* = K(1 - AA^*)^{1/2}$ where $K$ is a contraction in $B(\mathcal{H}_1,\mathcal{H}_2)$. So $B = (1 - AA^*)^{1/2}K^*$.

Let $X_0 = -LA^*K^*$. One has

$$\begin{bmatrix} A & B \\ C & X_0 \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & L \end{bmatrix} \begin{bmatrix} A & (1 - AA^*)^{1/2} \\ (1 - A^*A)^{1/2} & -A^* \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & K^* \end{bmatrix} = LUK^* .$$

The two terms $L'$ (in $B(\mathcal{H}_1^{[2]} \oplus \mathcal{H}_2)$) and $K'$ (in $B(\mathcal{H}_1 \oplus \mathcal{H}_2,\mathcal{H}_2^{[2]}))$ are contractions. The middle term $U$ is unitary since
\[ UU^* = \begin{bmatrix} I & A(1-AA^*)^{1/2} - (1-A^*A)^{1/2}A^* \\ (1-A^*A)^{1/2}A^* - A(1-A^*A)^{1/2} & I \end{bmatrix} \].

Now \( A(A^*A)^k = (A^*A)^kA^* \) for all \( k \geq 0 \), so \( Ap(A^*A) = p(AA^*)A \) for every polynomial \( p \). The identity \( UU^* = J^2 \) follows from approximately \( x^{1/2} \) by polynomials uniformly on \([0,1]\). Similarly, \( U^*U = J^2 \). Therefore, \( \| [A \ B] \| \leq 1 \).

It is clear that \( \| [A \ B] \| \) and \( \| \begin{bmatrix} A \\ C \end{bmatrix} \| \) are lower bounds for \( \| [A \ B] \| \) and hence \( X_0 \) minimizes this quantity. If \( A \) is compact, so is \( A^* \) and hence \( X_0 \) is compact.

9.2 Corollary. Let \( A_{ij} \) be operators in \( B(\mathcal{H}_j, \mathcal{H}_i) \) for \( j < i \). Let \( X_{ij} \) be operators in \( B(\mathcal{H}_j, \mathcal{H}_i) \) for \( i \leq j \). Then

\[
\begin{bmatrix}
X_{11} & X_{12} & \cdots & X_{1n} \\
A_{21} & X_{22} & \cdots & \cdots \\
A_{31} & A_{32} & \cdots & \cdots \\
\vdots & \vdots & \ddots & \cdots \\
A_{n1} & A_{n2} & \cdots & X_{nn}
\end{bmatrix}
\min_{X_{ij}} \| \begin{bmatrix} A_{k1} & A_{kk-1} \\ \vdots & \vdots \\ A_{n1} & A_{nk-1} \end{bmatrix} \| = \max_{2 \leq k \leq n} \| \begin{bmatrix} A_{k1} & A_{kk-1} \\ \vdots & \vdots \\ A_{n1} & A_{nk-1} \end{bmatrix} \| .
\]

Proof. Let \( \beta \) be the right hand side. Set \( X_{11}, \ldots, X_{1n} \), and \( X_{2n}, \ldots, X_{nn} \) all equal to zero. Choose \( X_{22} \) by Lemma 9.1 so that

\[
\| \begin{bmatrix} A_{21} & X_{22} \\
A_{31} & A_{32} \\
A_{n1} & A_{n2} \end{bmatrix} \| \leq \beta .
\]

With \( X_{22} \) fixed, one can now use Lemma 9.1 again to choose \( \begin{bmatrix} X_{23} \\ X_{33} \end{bmatrix} \) so that

\[
\| \begin{bmatrix} A_{21} & X_{22} & X_{23} \\
A_{31} & A_{32} & X_{33} \\
A_{n1} & A_{n2} & A_{n3} \end{bmatrix} \| \leq \beta .
\]

In this way, all \( X_{ij} \) are defined after \( (n-1) \) steps so that the norm is at most \( \beta \).
9.3 Corollary. Let $\mathcal{J}$ be a finite nest $\{0\} = N_0 < N_1 < \ldots < N_n = \mathcal{H}$. Then for every $A$ in $B(\mathcal{H})$,

$$\operatorname{dist}(A, T(\mathcal{J})) = \max_{0 \leq k \leq n} \| P(N_k)^\dagger AP(N_k) \|.$$ 

Proof. Decompose $\mathcal{H}$ as the direct sum of the $n$ blocks $N_k \ominus N_{k-1}$, $1 \leq k \leq n$. Then $A$ becomes an $n \times n$ matrix $(A_{ij})$. The operator $T$ in $T(\mathcal{J})$ have the form $(T_{ij})$ where $T_{ij} = 0$ for $j < i$. Thus

$$\inf \{ \| A - T \| : T \in T(\mathcal{J}) \} = \inf \| (X_{ij}) \|$$

where $X_{ij} = A_{ij}$ for $j < i$. By Corollary 9.2, this is precisely the quantity

$$\max_{0 \leq k \leq n} \| P(N_k)^\dagger AP(N_k) \|. \quad \square$$

9.4 Lemma. Let $\Lambda$ be a net, and suppose that $\{A_\lambda : \lambda \in \Lambda\}$ is a collection of weak*-closed linear subspaces of $B(\mathcal{H})$ such that $A_\mu \subseteq A_\lambda$ if $\mu \geq \lambda$. Let $\mathcal{A}$ be the intersection of $\{A_\lambda\}$. Then for $T$ in $B(\mathcal{H})$,

$$\operatorname{dist}(T, \mathcal{A}) = \sup_\Lambda \operatorname{dist}(T, A_\lambda) = \lim_\Lambda \operatorname{dist}(T, A_\lambda).$$

Proof. Since $A_\lambda$ is decreasing in $\lambda$, it is clear that

$$\operatorname{dist}(T, \mathcal{A}) \geq \sup_\Lambda \operatorname{dist}(T, A_\lambda) = \lim_\Lambda \operatorname{dist}(T, A_\lambda).$$

Let the supremum $\sup_\Lambda \operatorname{dist}(T, A_\lambda) = L$. For each $\lambda$, let

$$C_\lambda = \{ A \in \mathcal{A}, \| T - A \| \leq L \} = A \cap \{ A : \| T - A \| \leq L \}.$$ 

Then $C_\lambda$ is the intersection of a weak* closed and a weak* compact set, thus is weak*-compact. Moreover, $\{C_\lambda : \lambda \in \Lambda\}$ has the finite intersection property. For if $\lambda_1, \ldots, \lambda_n$ belong to $\Lambda$, there is some $\lambda_0$ in $\Lambda$ such that $\lambda_0 \geq \lambda_i$ for $1 \leq i \leq n$. So $\bigcap_{\lambda \in \Lambda} C_\lambda$ contains $C_{\lambda_0}$. By a standard compactness argument, there is an operator $A$ in the intersection of all the $C_\lambda$. Clearly, $A$ belongs to $\mathcal{A}$ and $\| T - A \| \leq L$. \quad \square

9.5 Theorem (Arveson's Distance Formula). Let $\mathcal{H}$ be a nest. For every $A$ in $B(\mathcal{H})$, $\operatorname{dist}(A, T(\mathcal{H})) = \sup_\mathcal{H} \| P(N)^\dagger AP(N) \|$.

Proof. The set $\{ T(\mathcal{J}) \}$ as $\mathcal{J}$ runs over finite subnets of $\mathcal{H}$ ordered by inclusion is a net of weakly closed subspaces with intersection $T(\mathcal{H})$. By Lemma 9.5 and Corollary 9.3,

$$\operatorname{dist}(A, T(\mathcal{H})) = \sup_\mathcal{J} \operatorname{dist}(A, T(\mathcal{J})) = \sup_\mathcal{H} \| P(N)^\dagger TT(N) \|. \quad \square$$
Now, we turn our attention to von Neumann algebras. If $A$ is a von Neumann algebra, then $A'' = \text{Alg Lat } A$ where Lat $A$ consists of the ranges of projections in $A'$. So, for $T$ in $B(A)$, one might hope for a connection between dist$(T(A))$, and the quantities

$$\sup\{\|P\perp TP\| : P \in \text{Proj}(A')\}$$

and

$$\sup\{\|TA - AT\| : A \in A', \|A\| \leq 1\}.$$ 

Define the derivation operation $\delta_T$ by $\delta_T(A) = TA - AT$. Note that

$$\delta_T(AB) = TAB - ATB + A\delta_T(B).$$

9.3 Theorem. Let $A$ be a von Neumann algebra such that $A'$ is AF. Then for $T$ in $B(A)$,

$$\sup_{P \in \text{Lat } A} \|P\perp TP\| \leq \frac{1}{2} \|\delta_T|A'|\| \leq \text{dist}(T, A) \leq \|\delta_T|A'|\| \leq 4 \sup_{P \in \text{Lat } A} \|P\perp TP\|.$$

Proof. Let $\Phi$ be an expectation onto $A$ provided by Theorem 8.3. Then since $\Phi(T)$ belongs to the weak$^*$ closed convex hull of $\{UTU^* : U \in U(A')\}$,

$$\text{dist}(T, A) \leq \|T - \Phi(T)\| \leq \sup\{\|T - UTU^*\| : U \in U(A')\} = \sup\{\|\delta_T(U)\| : U \in U(A')\} = \|\delta_T|A'|\|.$$

On the other hand, if $\|T - A\| = \text{dist}(T, A)$ for some $A$ in $A$, then

$$\|\delta_T|A'|\| = \sup\{\|(T - A)B - B(T - A)\| : B \in A', \|B\| \leq 1\} \leq 2\|T - A\| = 2\text{dist}(T, A).$$

When $P$ is a projection in $\text{Lat } A$, $2P - I$ is a unitary in $A'$. So

$$\max\{\|PTP\perp\|, \|P\perp TP\|\} = \|TP - PT\| = \frac{1}{2}\|T(2P - I) - (2P - I)T\| \leq \frac{1}{2}\|\delta_T|A'|\|.$$ 

On the other hand, the extreme points of the unit ball of the self-adjoint operators in $A'$ are precisely $2P - I$ for $P$ in $\text{Lat } A$. Thus

$$\sup\{\|P\perp TP\| = \frac{1}{2}\|\delta_T|A'|\|.$$ 

Every norm one element of $A'$ can be written $X = A + iB$ when $A, B$ are self-adjoint contractions. So

$$\|\delta_T|A'|\| \leq 2\|\delta_T|A_{\text{SA}}'|\| \leq 4 \sup_{P \in \text{Lat } A} \|P\perp TP\|. \quad \blacksquare$$
9.7 Example. Consider the $3 \times 3$ diagonal algebra $D$ and the operator $T = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$. As $D = D'$, one finds $\text{Lat} \ D = \text{Proj}(D)$ consists of 

$\{0, P_i, P_i^\perp, I, i=1,2,3\}$ where $P_i$ is the projection onto the $i$th basis vector.

So $\sup_{P \in \text{Lat} \ D} \|P^\perp TP\| = \|(1,1)\| = \sqrt{2}$. Suppose that $D$ is diagonal and $\|T-D\| = \text{dist}(T,D)$. Now $\|T-UDU^*\| = \|T-D\|$ for every permutation matrix $U$ in $S_3$. Averaging over this group leaves $T$ fixed, but converts $D$ to a scalar. So

$$\text{dist}(T,D) = \inf\{\|T-\lambda I\| : \lambda \in \mathbb{C}\}.$$

Now $T$ is self-adjoint with $\sigma(T) = \{0,3\}$. So $\|T-\lambda I\| = \max\{|\lambda|, |3-\lambda|\} \geq 3/2$; and $\text{dist}(T,D) = \|T-3/2I\| = 3/2$.

Thus $\|\delta_T |D\| \leq 3$. Let $W = \begin{bmatrix} 1 & 0 & 0 \\ 0 & \omega & 0 \\ 0 & 0 & \bar{\omega} \end{bmatrix}$ Where $\omega = \frac{1}{2} + \frac{\sqrt{3}}{2} i$. Then $W$ is unitary, so

$$\|\delta_T |D\| \geq \|TW-WT\| = \|W^*TW-T\|$$

$$\geq \| \begin{bmatrix} 0 & 1-\omega & 1-\omega \\ 1-\omega & 0 & 1-\bar{\omega} \\ 1-\bar{\omega} & 1-\omega & 0 \end{bmatrix} \begin{bmatrix} 1/\sqrt{3} \\ 1/\sqrt{3} \\ 1/\sqrt{3} \end{bmatrix} \| = \| \begin{bmatrix} \sqrt{3} \\ \sqrt{3} \\ \sqrt{3} \end{bmatrix} \| = 3 .$$

So three of the four inequalities in Theorem 9.6 are strict in this example. $\blacksquare$

With some more work, the constant $4$ can be reduced to $2$ if $A$ or $A'$ is abelian.

9.8 Lemma. If $A$ is a von Neumann algebra with abelian commutant, then

$$\text{dist}(T,A) \leq 2\sup\{\|P^\perp TP\| : P \in \text{Lat} \ A\}$$

for $T$ in $B(\mathcal{A})$.

Proof. Let $P$ and $Q$ belong to $\text{Lat} \ A$. Then $P+Q-PI$ is the projection in $\text{Lat} \ A$ onto the span of $P\mathcal{N}$ and $Q\mathcal{N}$. So

$$(2P-I)(2Q-I) = I-2(P+Q-PI) = 2(P+Q-PI)^\perp-I .$$

Thus $\mathcal{G} = \{2P-I : P \in \text{Lat} \ A\}$ is a subgroup of $U(A')$. The projections span $A'$, hence $\mathcal{G}' = A$. The proof of Corollary 8.8 yields an expectation $\Phi$ of $B(\mathcal{N})$ onto $A$ such that $\Phi(X)$ belongs to the weak$^*$ closed convex hull of $\{UXU^*: U \in \mathcal{G}\}$. Hence
\[ \text{dist}(T,A) \leq \|T - \Phi(T)\| \leq \sup_{\mathcal{P} \in \text{Lat}A} \|T - (2P - I)T(2P - I)\| \]
\[ = \sup_{\mathcal{P} \in \text{Lat}A} \|T(2P - I) - (2P - I)T\| = 2 \sup_{\mathcal{P} \in \text{Lat}A} \|P \perp TP\| . \]

The last equality comes from the proof of Theorem 9.6. \hfill \blacksquare

9.9 Lemma. If 0 is in the convex hull of a subset \( \Lambda \) of \( \mathbb{C} \), then 0 is in the convex hull of three points of \( \Lambda \). In particular, if \( \Lambda = \{\lambda_n, n \geq 1\} \) and \( \sum_{n=1}^{\infty} \lambda_n = 0 \), then 0 is in the convex hull of \( \Lambda \).

Proof. The convex hull of any finite subset of \( \mathbb{C} \) is a polygon with vertices \( \lambda_0, \ldots, \lambda_n \) in order around the boundary. It is the union of the triangles with vertices \( \{\lambda_0, \lambda_j, \lambda_{j+1}\} \) for \( 1 \leq j \leq n-1 \). Thus the convex hull of \( \Lambda \) coincides with the convex combinations of 3 point subsets of \( \Lambda \). If 0 is not in then convex hull of \( \Lambda \), there is a scalar \( e^{i\theta} \) such that \( \text{Re}(e^{i\theta} \lambda_n) \geq 0 \) for all \( \lambda_n \) in \( \Lambda \). But \( 0 = \text{Re}(e^{i\theta} \sum_{n \geq 1} \lambda_n) = \sum_{n \geq 1} \text{Re}(e^{i\theta} \lambda_n) \) forces \( \lambda_n \) to be on the line \( \text{Re}(e^{i\theta} z) = 0 \). So \( \sum_{n \geq 1} \lambda_n = 0 \) implies \( \text{Im}(e^{i\theta} \lambda_n) \) takes both signs, and so 0 is in the convex hull. \hfill \blacksquare

9.10 Lemma. If \( K \in C_j \), and \( tr(K) = 0 \), then there is a unit vector \( e \) such that \( (Ke,e) = 0 \).

Proof. Choose an orthonormal basis \( \{e_n, n \geq 1\} \) and let \( \lambda_n = (Ke_n,e_n) \). Then \( 0 = trK = \sum \lambda_n \). By the preceding lemma, it may be supposed that 0 is in the convex hull of \( \lambda_1, \lambda_2 \) and \( \lambda_3 \). Each \( \lambda_i \) belongs to the numerical range \( W(K) = \{(Kx,x) : \|x\| = 1\} \). So it suffices to prove that \( W(K) \) is convex. To this end, consider \((Kx_1,x_1)\) and \((Kx_2,x_2)\). They belong to \( W(K) \) also, where \( K_0 \) is the compression of \( K \) to \( \text{span}(x_1,x_2) \). Since \( W(K_0) \) is a subset of \( W(K) \), it suffices to show that \( W(K_0) \) is convex. It is clear that if \( a, b \) are scalars and \( U \) is unitary,
\[ W(aUK_0U^* + bI) = aW(K_0) + b . \]
So put \( K_0 \) in upper triangular form and scale it so that \( trK_0 = 0 \), and \( \sigma(K_0) = \{0\} \) or \( \{-1,+1\} \), and \( (Ke_0,e_0) \geq 0 \). This reduces our problem to computing \( W\begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix} \) and \( W\begin{bmatrix} 1 & 2r \\ 0 & -1 \end{bmatrix} \) where \( r \geq 0 \). The first is the closed disc of radius \( 1/2 \), centre 0 and the latter is the set
\{\cos 2\theta + re^{i\alpha}\sin 2\theta : 0 \leq \theta, \alpha \leq 2\pi\}

which can be shown to be the ellipse \(\{x + iy : -\frac{x^2}{1+r^2} + \frac{y^2}{r^2} \leq 1\}\) (See Exercise 9.2). Both are convex as claimed.

\section*{9.11 Lemma.} Let \(\mathcal{A}\) be an abelian von Neumann algebra. Then for \(T\) in \(\mathcal{B}(\mathcal{K})\),

\[
\text{dist}(T, \mathcal{A}) = \sup \text{dist}(T, \mathcal{M})
\]

where the sup is taken over all maximal abelian von Neumann algebras \(\mathcal{M}\) containing \(\mathcal{A}\).

\textbf{Proof.} Since \(\mathcal{A}\) is weak* closed, the Hahn-Banach Theorem provides a weak* continuous linear function \(\phi\) of norm one which annihilates \(\mathcal{A}\) and

\[
\phi(T) = \text{dist}(T, \mathcal{A})
\]

By Theorem 1.15, \(\phi(X) = \text{tr}(XK)\) for some trace class operator \(K\) with \(\|K\| = 1\). Using Zorn's Lemma, one can find a maximal, abelian self-adjoint algebra \(\mathcal{M}\) in \(\ker \phi\). It suffices to show that \(\mathcal{M}\) is maximal abelian in \(\mathcal{B}(\mathcal{K})\).

If not, then by Theorem 7.14, \(\mathcal{M}\) contains a projection \(P\) of uniform multiplicity \(n \geq 2\). If \(P\) dominates a minimal projection, we may assume that \(P\) itself is minimal. In this case, \(\mathcal{M}_0 = \mathcal{M} |_{\mathcal{P}_\mathcal{K}}\) consists of the scalars in \(\mathcal{M}_\mathcal{K}\) (or \(\mathcal{B}(\mathcal{K})\) if \(n = \mathbb{N}_0\)). Otherwise, \(\mathcal{M}_0 |_{\mathcal{P}_\mathcal{K}}\) is unitarily equivalent to \(L^\infty(\mu)|^{[n]}\) acting on \(L^2(\mu)|^{[n]}\) for a non-atomic measure \(\mu\). Let \(\phi_0\) be the restriction of \(\phi\) to \(\mathcal{B}(\mathcal{P}_\mathcal{K})\) given by \(\phi_0(X) = \text{tr}(XK_0)\), and note that it annihilates \(\mathcal{M}_0\).

In the first case, \(\text{tr}K_0 = 0\). By Lemma 9.9, there is a rank one projection \(E < P\) such that \(\text{tr}EK_0 = 0\). It is easy to check that the von Neumann algebra generated by \(\mathcal{M}\) and \(E\) is just \(\{A + \lambda E : A \in \mathcal{M}, \lambda \in \mathbb{C}\}\). So \(\phi\) annihilates this larger algebra, contrary to hypothesis.

In the continuous case, consider the restriction of \(\phi_0\) to the \(n \times n\) matrices with coefficients in \(L^\infty\). Let \(\phi_{ij}\) be the restriction of \(\phi_0\) to the copy of \(L^\infty(\mu)\) in the \(ij\) component of the matrix. Since \(\phi_{ij}\) is weak* continuous and \(L^\infty(\mu) = L^1(\mu)^*\), there is an \(L^1(\mu)\) function \(f_{ij}\) such that \(\phi_{ij}(h) = \int hf_{ij}d\mu\). Since \(\phi_0 |_{\mathcal{M}_0} = 0\), \(\sum_{i \geq 1} f_{ii} = 0\). The atomic case can be repeated "pointwise" provided care is taken to keep all the functions Borel. First choose Borel representatives \(f_{ij}(x)\). Then \(\sum_{i \geq 1} f_{ii}(x) = 0\), and converges absolutely, except on a set of measure zero. By Lemma 9.9, for each \(x\), 0 is in the convex hull of some triple \(f_{i_1j_1}(x), f_{i_2j_2}(x), f_{i_3j_3}(x)\). The convex hull of a finite set is a Borel function of the set, so
\{x: 0 \text{ belongs to } \text{conv}\{f_{i,i}(x), f_{i,j}(x), f_{i,k}(x)\}\}

is Borel for each triple. Thus there is one triple for which this has positive measure. It may be assumed to be 1,2,3 (or a pair 1,2 if \(n = 2\)). By making \(P\) smaller, it may be supposed that this holds for all \(x\).

By Lemma 9.10, there are scalars \(\alpha_i(x), \alpha_0(x)\) and \(\alpha_3(x)\) such that
\[
\sum_{i=1}^{3} |\alpha_i(x)|^2 = 1 \quad \text{and} \quad \sum_{i=1}^{3} \sum_{j=1}^{3} f_{ij}(x)\overline{\alpha_i(x)}\alpha_j(x) = 0.
\]

To make this choice Borel, we insist that \(\alpha_0(x) \geq 0\) and maximal, \(\alpha_3(x) = r_3(x)e^{i\theta_3(x)}\) where \(0 \leq \theta_3(x)\) is minimal and \(r_3(x)\) is maximal subject to earlier restraints, and likewise for \(\alpha_0(x)\). (Note that if \(n = 2\), then \(\alpha_0\) does not appear.) Let \(E\) be the projection in \(\mathcal{M}_n \otimes L^a(\mu)\) given by \(E_{ij} = M_{\alpha_j\alpha_i}\) for \(1 \leq i, j \leq 3\) and \(E_{ij} = 0\) otherwise. This has been constructed so that if \(P_k\) is the diagonal matrix in \(\mathcal{M}_0\) corresponding to the characteristic function of any Borel set \(\Omega\), then
\[
\phi_0(P_k E) = tr(P_k E K_0) = \int_0^1 \sum_{i=1}^{3} \sum_{j=1}^{3} f_{ij}(x)\overline{\alpha_i(x)}\alpha_j(x) d \mu(x) = 0.
\]

Thus \(\phi_0\) annihilates the von Neumann algebra generated by \(\mathcal{M}_0\) and \(E\), and hence \(\phi\) annihilates \(W'(\mathcal{M}, E)\). This contradicts the maximality of \(\mathcal{M}\).

Thus \(\mathcal{M}\) is maximal abelian, and since \(\phi\) annihilates \(\mathcal{M}\),
\[
dist(T, \mathcal{A}) \geq dist(T, \mathcal{M}) \geq \phi(T) \geq dist(T, \mathcal{A}) \quad .
\]

9.12 Theorem. Let \(\mathcal{A}\) be an abelian von Neumann algebra. For \(T\) in \(B(\mathcal{H})\),
\[
dist(T, \mathcal{A}) \leq 2 \sup\{\|P^T\|: P \in \text{Lat } \mathcal{A}\} \quad .
\]

Proof. By Lemma 9.11 and Lemma 9.8, there is a m.a.s.a. \(\mathcal{M}\) such that
\[
dist(T, \mathcal{A}) = dist(T, \mathcal{M}) \leq 2 \sup_{P \in \text{Lat } \mathcal{M}} \|P^T\| \leq 2 \sup_{P \in \text{Lat } \mathcal{A}} \|P^T\| \quad .
\]

We complete this chapter with a sharp formula for the distance to the scalar operators. Define the maximal numerical range of an operator \(T\) to be
\[
W_0(T) = \{\lambda \in \mathbb{C}: \exists x_n \in \mathcal{H}, \|x_n\| = 1, \lim\langleTx_n, x_n\rangle = \lambda \text{ and } \lim\|Tx_n\| = \|T\|\}.
\]
9.13 Lemma. $W_0(T)$ is a closed convex subset of $W(T)$.

**Proof.** One need only verify that $W_0(T)$ is convex. Normalize so that $\|T\| = 1$. Let $\lambda$ and $\mu$ be points in $W_0(T)$ determined by sequences $\{x_n\}$ and $\{y_n\}$ respectively, and let $\lambda_n = (Tx_n, x_n)$ and $\mu_n = (Ty_n, y_n)$. If $v_n = e^{i\phi} y_n - x_n$,

$$
\mu_n = (Tx_n + v_n, x_n + v_n) = \lambda_n + (Tx_n, v_n) + (Tv_n, x_n + v_n)
$$

Hence $|\mu_n - \lambda_n| \leq 2 \|v_n\|$. Choose $\phi$ so that

$$
|\langle x_n, y_n \rangle| = \langle x_n, e^{i\phi} y_n \rangle = 1 - \frac{1}{2} \|x_n - e^{i\phi} y_n\|^2
$$

$$
\leq 1 - \frac{1}{8} |\mu_n - \lambda_n|^2 \leq \theta < 1
$$

for $n$ large. Let $\epsilon_n = \max(1-\|Tx_n\|^2, 1-\|Ty_n\|^2)$. Then

$$
\|(I-T^\ast T)x_n\|^2 = \|x_n\|^2 - 2\Re(T^\ast Tx_n, x_n) + \|T^\ast Tx_n\|^2
$$

$$
\leq 2(1-\|Tx_n\|^2) \leq 2\epsilon_n
$$

Similarly, $\|(I-T^\ast T)y_n\|^2 \leq 2\epsilon_n$. If $u_n$ is a unit vector in $\text{span}\{x_n, y_n\}$, write $u_n = a_n x_n + b_n y_n$. Then

$$
1 = \|u_n\|^2 = |a_n|^2 + |b_n|^2 + 2\Re a_n \overline{b_n}(x_n, y_n)
$$

$$
\geq |a_n|^2 + |b_n|^2 - 2|a_n||b_n|\theta
$$

$$
= (1-\theta)(|a_n|^2 + |b_n|^2) + \theta(|a_n| - |b_n|)^2
$$

Hence $|a_n|^2 + |b_n|^2 \leq (1-\theta)^{-1}$. So by the Cauchy-Schwartz inequality,

$$
\|(I-T^\ast T)u_n\| \leq \|u_n\| \|(I-T^\ast T)x_n\| + \|b_n\| \|(I-T^\ast T)y_n\|
$$

$$
\leq 2(1-\theta)^{-\frac{1}{2}} \epsilon_n^{\frac{1}{2}}
$$

Hence

$$
\|Tu_n\|^2 = \|u_n\|^2 - \|(I-T^\ast T)u_n, u_n\| \geq 1 - 2(1-\theta)^{-\frac{1}{2}} \epsilon_n^{\frac{1}{2}}
$$

Now let $\eta$ belong to the convex hull of $\lambda$ and $\mu$, and let $\eta_n$ belong to the convex hull of $\lambda_n$ and $\mu_n$ with $\eta = \lim \eta_n$. Let $P_n$ be the projection onto $\text{span}\{x_n, y_n\}$, and set $T_n = P_n T |P_n \mathcal{N}$. Then $\lambda_n$ and $\mu_n$ belong to $W(T_n)$, which is convex (Lemma 9.10 and Exercise 9.2). So there is a unit vector $u_n$ in $\text{span}\{x_n, y_n\}$ such that $\langle Tu_n, u_n \rangle = (T_n u_n, u_n) = \eta_n$. By the previous paragraph, $\|Tu_n\|$ tends to 1. So $\eta$ belongs to $W_0(T)$. Thus $W_0(T)$ is convex.
9.14 Lemma. If \( \| T \| = \text{dist}(T, \mathcal{E}I) \), then 0 belongs to \( W_0(T) \).

Proof. Assume \( W_0(T) \) does not contain 0. As \( W_0(T) \) is convex and closed, one can replace \( T \) by a scalar multiple so that \( \text{Re}W_0(T) \geq 1 \). Let 
\[
S = \{ x \in \mathcal{H} : \| x \| = 1 \text{ and } \text{Re}(Tx,x) \leq 1/2 \} ,
\]
and let \( r = \sup \{ \| Tx \| : x \in S \} \). Then \( r < \| T \| \), so 
\[
\mu = \min \{ 1/2, (\| T \| - r)/2 \}
\]
is positive. Consider \( T - \mu I \). For \( x \) in \( S \), 
\[
\| (T - \mu I)x \| \leq \| Tx \| + \mu \leq r + (\| T \| - r)/2 < \| T \| .
\]
For any unit vector \( x \) not in \( S \), \( \text{Re}(Tx,x) > 1/2 \), so 
\[
\| (T - \mu I)x \|^2 = \| Tx \|^2 + \mu^2 - 2\mu \text{Re}(Tx,x) < \| T \|^2 - \mu(1 - \mu) .
\]
Hence \( \| T - \mu I \| < \| T \| \). This contradiction establishes the lemma. \( \square \)

9.15 Theorem. For all \( T \) in \( B(\mathcal{H}) \), \( \text{dist}(T, \mathcal{E}I) = \frac{\lambda}{2} \| \delta_T \| . \)

Proof. By compactness, there is a scalar \( \lambda \) so that \( \| T - \lambda I \| = \text{dist}(T, \mathcal{E}I) \). Without loss of generality, \( \lambda = 0 \) and \( \| T \| = 1 \). So by Lemma 9.14, 0 belongs to \( W_0(T) \). Let \( \{ x_n \} \) be unit vectors such that \( \lim \langle Tx_n, x_n \rangle = 0 \), and \( y_n = Tx_n \) have \( \lim \| y_n \| = 1 \). Note that \( (T^* y_n, x_n) = (y_n, y_n) \) tends to 1. Let \( A_n = x_n \otimes x_n^* - y_n \otimes y_n^* \). Clearly, \( \| A_n \| \leq 1 \). Moreover 
\[
| \langle \delta_T(A_n)x_n, y_n \rangle | = \left| \langle (y_n \otimes x_n^* - Ty_n \otimes y_n^* - x_n \otimes (T^* y_n))^* + y_n \otimes (T^* y_n)^*x_n, y_n \rangle \right| 
\]
\[
\geq \| y_n \|^2 - 2 \| (x_n, y_n) \| + \| y_n \|^4.
\]
So 
\[
\| \delta_T \| \geq \sup \| \delta_T(A_n) \| \geq 2 = 2 \text{dist}(T, \mathcal{E}I) .
\]
On the other hand, for all \( A \)
\[
\| \delta_T(A) \| \leq \| TA \| + \| AT \| \leq 2 \| T \| \| A \| = 2 \text{dist}(T, \mathcal{E}I) \| A \| .
\]
Thus \( \| \delta_T \| = 2 \text{dist}(T, \mathcal{E}I) . \) \( \square \)
Notes and Remarks.

Lemma 9.1 was proved by Parrott [2] using a lifting theorem of Sz. Nagy and Foias [1]. It was proved independently by Davis, Kahane, Weinburger [1] and it is their proof provided here. They explicitly give all solutions $X$ satisfying $\|A B X\| = \gamma$. Theorem 9.5 is due to Arveson [7]. The proof given here is due to Power [1]. Another proof due to Lance [2] will be given in Chapter 16. Theorem 9.6 is due to Christensen [4]. Example 9.7 has been credited to Choi in Davidson [1]. Theorem 9.12 is due to Rosenthal [1]. The essence of Lemma 9.10 is that the numerical range of an operator is convex. This is due to Hadamard (c.f. Halmos [2]). Theorem 9.15 is due to Stampfli [1].

Exercises.

9.1 (Arveson)

(i) Let $\phi$ be a weak* continuous linear functional on $B(H)$. Show that there are vectors $x$ and $y$ in $H^{\infty}$ such that

$$\phi(A) = (A^{(\infty)}x, y).$$

(ii) If $A$ is a weak* closed, unital subalgebra of $B(H)$, show that for all $T$ in $B(H),$

$$\text{dist}(T, A) = \sup \{\|P \bot T^{(\infty)}P\| : P \in \text{Lat } H^{\infty}\}.$$

(iii) Let $F$ be a finite nest $\{0\} = F_0 < \ldots < F_n = H$ with atoms $A_k = F_k \ominus F_{k-1}$. Let $P$ belong to $\text{Lat } (F^{(\infty)})$. Show that this belongs to $F^{\infty} \otimes B(H)$ and thus has the form

$$\sum_{i=1}^{n} P(A_i) \otimes P_i$$

where $P_i$ are projections. Show that $P_k \geq P_{k+1}$ for $1 \leq k \leq n-1$.

(iv) Rewrite $P$ as $\sum_{j=1}^{n} P(F_j) \otimes Q_j$ where $Q_j$ are pairwise orthogonal. Combine this with (ii) to prove Corollary 9.3.

9.2 Show that $x + iy$ belongs to $W\begin{pmatrix} 1 & 2r \\ 0 & -1 \end{pmatrix}$ if and only if $(x - c)^2 + y^2 = r^2(1 - c^2)$ has a solution $c$ in $[-1, 1]$. Compute the discriminant of this quadratic in $c$ and thereby deduce that the numerical range is the ellipse $\{x + iy : \frac{x^2}{1 + r^2} + \frac{y^2}{r^2} \leq 1\}$. 
9.3 (Davidson-Power) Let \( \mathcal{N} \) be a nest of order type \( \mathbb{N} \cup \{\infty\}, \{-\infty\} \cup \mathbb{N}, \) or \( \{-\infty\} \cup \mathbb{Z} \cup \{+\infty\} \). Given \( K \) compact, find \( T \) in \( \mathcal{T}(\mathcal{N}) \cap K \) such that \( \text{dist}(K, \mathcal{T}(\mathcal{N})) = \|K - T\| \). 

**Hint:** Reduce to the finite nest case by finding \( N_1 < N_2 \) in \( \mathcal{N} \) so that \( \|KP(N_1)\| \leq \frac{\|K\|}{2} \|\text{dist}(K, \mathcal{T}(\mathcal{N}))\| \) and \( \|P(N_2) - K\| \leq \frac{\|K\|}{2} \|\text{dist}(K, \mathcal{T}(\mathcal{N}))\| \).

9.4 (Davidson-Power)

(i) Let \( \mathcal{N} \) be the Volterra nest on \( L^2(0,1) \) and let \( K = 1 \otimes 1^* \). Show that \( \frac{\|K\|}{2} = \text{dist}(K, \mathcal{T}(\mathcal{N})) < \|K - T\| \) for every compact \( T \) in \( \mathcal{T}(\mathcal{N}) \). 

**Hint:** Let \( x = \sqrt{2}\chi_{[\frac{1}{4}, 1]} \). Prove that if \( \|K - T\| = \frac{\|K\|}{2} \), then \( TP(N_t)x = \frac{\|K\|}{2} P(N_t)x \) for all \( t \) in \( [\frac{1}{4}, 1] \).

(ii) \( \text{dist}(K, \mathcal{T}(\mathcal{N})) = \text{dist}(V^*, \mathcal{T}(\mathcal{N})) \) where \( V \) is the Volterra operator of Chapter 5. Let \( D \) be the diagonal operator which is multiplication by \( f(x) = \min\{x, 1-x\} \). Show that \( \|V^* - D\| = \frac{\|K\|}{2} \).

9.5 (Davidson-Power) Let \( \mathcal{N} \) be given by an increasing sequence of finite dimensional subspaces sense in \( \mathcal{H} \). Prove that for \( A \) in \( \mathbb{B}(\mathcal{H}) \),

\[
\text{dist}(A, \mathcal{T}(\mathcal{N}) \cap K) = \max\{\|A\|_{\mathcal{T}}, \text{dist}(T, \mathcal{T}(\mathcal{N}))\}.
\]

9.6 (i) Let \( A \) be a reflexive algebra. For \( T \) in \( \mathbb{B}(\mathcal{H}) \), show that

\[
\text{dist}(T, \mathcal{A}) \geq \sup\{\|P^1TP\|: P \in \text{Lat} \mathcal{A}\}.
\]

(ii) Let \( A_\theta \) be the algebra of \( 2 \times 2 \) matrices with \( e_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix} \) and

\[
e_\theta = \begin{pmatrix} \cos \theta \\ \sin \theta \end{pmatrix} \text{as eigenvectors. Find Lat } A_\theta. \text{ Let } E = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \text{. Compare dist}(E, A_\theta) \text{ to max}\{\|P^1EP\|: P \in \text{Lat } A_\theta\}.
\]

(iii) (Kraus-Larson) Let \( \mathcal{A} = \sum_{n=1}^{\infty} \mathcal{A}_n \). Prove that \( \mathcal{A} \) is reflexive. Find operators \( E_n \) such that

\[
\lim_{n \to \infty} \frac{\max\{\|P^1E_nP\|: P \in \text{Lat } \mathcal{A}\}}{\text{dist}(E_n, \mathcal{A})} = 0.
\]
10. Derivations of C*-Algebras

A bimodule of a Banach algebra $\mathcal{A}$ is a Banach space $\mathcal{E}$ which is a 2-sided module over $\mathcal{A}$ satisfying $\|AE\| \leq \|A\| \|E\|$ and $\|EA\| \leq \|E\| \|A\|$ for all $A$ in $\mathcal{A}$ and $E$ in $\mathcal{E}$. A derivation $\delta$ of an algebra $\mathcal{A}$ into an $\mathcal{A}$-bimodule $\mathcal{E}$ is a linear map $\delta$ satisfying $\delta(AB) = \delta(A)B + A\delta(B)$ for all $A$ and $B$ in $\mathcal{A}$. The derivation is called inner if there is an element $E$ in $\mathcal{E}$ such that $\delta(A) = E\delta(A) = AE - EA$. For our purposes, the bimodules of interest will be $\mathcal{A}$, $B(\mathcal{H})$, and $K$.

10.1 Lemma. Let $A$ and $B$ belong to a C*-algebra $\mathcal{A}$. If $B$ is positive, $\|B\| \leq 1$, and $AA^* \leq B^4$, then there is an element $C$ in $\mathcal{A}$ such that $A = BC$ and $\|C\| \leq 1$.

Proof. If $\mathcal{A}$ has no unit, then let $\mathcal{A}_1$ be the C*-algebra with unit adjointed. Define $C_t = (B + tl)^{-1}A$ and note that this belongs to $\mathcal{A}$, and

$$C_tC_t^* = (B + tl)^{-1}AA^*(B + tl)^{-1} \leq (B + tl)^{-1}B^4(B + tl)^{-1} \leq B^2 \leq I.$$ 

So $\|C_t\| \leq 1$. It will be shown that $C = \lim_{t \to 0} C_t$ exists.

$$C_tC_t^* - C_t = (B + sl)^{-1}(B + tl)^{-1}(B + tl - B - sl)A$$

$$= (t-s)(B + sl)^{-1}(B + tl)^{-1}A.$$ 

Hence

$$\|C_tC_t^* - C_t\|^2 = (t-s)^2\|AA^*(B + tl)^{-1}(B + sl)^{-1}\|$$

$$\leq (t-s)^2\|AA^*(B + tl)^{-1}B^4(B + tl)^{-1}(B + sl)^{-1}\|$$

$$\leq (t-s)^2.$$ 

So $C_t$ is Cauchy, and $C$ exists as claimed. Furthermore,

$$BC = \lim_{t \to 0} B(B + tl)^{-1}A = \lim_{t \to 0} A - tC_t = A.$$ 

10.2 Lemma. Let $\mathcal{A}$ be an infinite dimensional C*-algebra. Then $\mathcal{A}$ contains a self-adjoint element $A$ with infinite spectrum.

Proof. It clearly does not hurt to adjoin a unit, so we assume that $\mathcal{A}$ contains an identity $I$. Let $\mathcal{M}$ be a maximal abelian subalgebra. Then $\mathcal{M}$ is isomorphic to $C(X)$ for a compact Hausdorff space $X$. If $X$ is infinite,
then $\mathcal{M}$ contains an element $A$ corresponding to a real function with infinite range, and thus infinite spectrum. If $X$ is finite, $\mathcal{M}$ contains a finite set $E_1, \ldots, E_n$ of minimal projections with $\sum_{j=1}^n E_j = I$. Now, $E_i A E_j$ is a $C^*$-algebra in which $\mathcal{O} E_j$ is a maximal abelian subalgebra. Hence $E_i A E_j = \mathcal{O} E_j$. If $E_i A E_j$ is not zero, choose $A = E_i A E_j$ of norm one. Then $A^* A = E_j$ and $A A^* = E_i$. Let $B = E_i B E_j$. Then there is a scalar $\lambda$ so that $B A^* = \lambda A A^*$. Thus

$$B - \lambda A = (B - \lambda A) E_j = (B A^* - \lambda A A^*) A = 0.$$ 

So $E_i A E_j$ is one dimensional, and hence $\mathcal{A}$ is at most $n^2$ dimensional. 

10.3 Theorem. Every derivation $\delta$ of a $C^*$-algebra into a bimodule $\mathcal{E}$ is continuous.

Proof. Let $J$ be the set of elements $J$ in $\mathcal{A}$ such that the map $D_J$ taking $T$ to $\delta(JT)$ is continuous. Clearly $J$ is a right ideal. Also

$$\delta(AJT) = A \delta(JT) + \delta(A)JT$$

is continuous in $T$ for every $A$ in $\mathcal{A}$ and $J$ in $J$. So $J$ is also a left ideal. To show that $J$ is closed, consider $J_n$ in $J$ converging to $J$. Then

$$D_J(T) = \delta(JT) = J \delta(T) + \delta(J)T$$

$$= \lim_{n \to \infty} J_n \delta(T) + \delta(J)T$$

$$= \lim_{n \to \infty} D_{J_n}(T) - \delta(J_n)T + \delta(J)T.$$ 

So $D_J$ is the pointwise limit of continuous maps. Thus $D_J$ is continuous by the Uniform Boundedness Principle.

Next, we show that $\delta$ is continuous on $J$. For otherwise, there are $J_n$ in $J$, $n \geq 1$, such that $\|J_n\| \leq 2^{-n}$ and $\|\delta(J_n)\| \geq n$. Thus

$$B = (\sum_{n \geq 1} J_n J_n^*)$$

is a positive element of $J$ with $\|B\| \leq 1$. By Lemma 10.1, there are elements $C_n$ in $J$ with $\|C_n\| \leq 1$ such that $J_n = BC_n$. Hence

$$\|D_B(C_n)\| = \|\delta(BC_n)\| = \|\delta(J_n)\| \geq n$$

contradicting the continuity of $D_B$. Let $M = \|\delta \|$. 

Suppose that $\mathcal{A}/J$ is infinite dimensional. Then by Lemma 10.2, it contains a self-adjoint element $A$ so that $C^*(A)$ is isomorphic to $C_0(X)$ where $X$ is an infinite, compact subset of $[-1,1]$. There are countably many positive functions $f_j$, $j \geq 1$ in $C_0(X)$ such that $f_j f_k = 0$ if $j \neq k$ and $f_j(A) \neq 0$. Let $A_j$ be positive, norm one elements of $\mathcal{A}$ such that $A_j + J$ is a scalar multiple of $f_j(A)$. Then $A_j^2 A_k$ belongs to $J$ for $j \neq k$, but $A_j^2 + J = f_j(A)^2 \neq 0$. Since $A_j^2$ is not in $J$, $D_{A_j}$ is unbounded. Thus one
can choose $T_j$ in $A$ with $\|T_j\| \leq 2^{-j}$ and $\|\delta(A_j T_j)\| \geq \|\delta(A_j)\| + j$. Let $X = \sum A_j T_j$. Then $A_k X = A_k^2 T_k + J_k$ where $J_k = \sum_{j \geq k} A_k A_j T_j$ belongs to $J$, and $\|J_k\| \leq 1$. So

$$\|\delta(X)\| \geq \|A_k \delta(X)\| = \|\delta(A_k X) - \delta(A_k) X\|$$

$$\geq \|\delta(A_k^2 T_k)\| - \|\delta(J_k)\| - \|\delta(A_k)\| \|X\|$$

$$\geq \|\delta(A_k)\| + k - M - \|\delta(A_k)\| = k - M.$$ 

But $k$ is arbitrary, and so this is impossible.

Hence $A/J$ is finite dimensional. As $\delta$ is continuous on $J$, it must be continuous on all of $A$.

Let $A$ be a $C^*$-algebra acting on a Hilbert space $H$. An $A$-bimodule $E$ which is the dual of a Banach space $E_*$ is a normal dual bimodule if the maps $A \to AE$ and $A \to EA$ are continuous from the weak* topology on $A$ to the weak* topology on $E$. It is easy to extend the module action of $A$ to all of $A''$ by the weak* continuity. To study the weak* continuity of derivations, we first need some basic facts about the double dual of a $C^*$-algebra.

10.4 Theorem. Let $A$ be a $C^*$-algebra. Then the second dual $A''$ is isometrically isomorphic to a von Neumann algebra $M$, and this isomorphism is a homeomorphism of $A''$ with its weak* topology onto $M$ with its weak* topology.

Proof. For each state $f$ on $A$, the GNS construction provides a representation $(H_f, \pi_f)$ with a cyclic vector $\xi_f$ such that $(\pi_f(A) \xi_f, \xi_f) = f(A)$ for all $A$ in $A$. The representation $\pi = \sum \sigma_f$ on $H = \sum \sigma_f$ is the universal atomic representation. Let $M$ denote the weak operator closure of $\pi(A)$. This is known as the universal enveloping von Neumann algebra of $A$. Every positive linear functional on $A$ is given by a vector state, and thus extends to be a weak* continuous functional on $M$. Conversely, if $\phi$ is a weak* continuous functional on $M$, then $\phi$ is determined by its restriction to $A$. Because the unit ball of $A$ is weak* dense in the ball for $M$ (Kaplansky’s Density Theorem), $\|\phi\| = \|\phi\|_A$. So $A''$ is isometrically isomorphic to $M_*$, the space of weak* continuous functionals on $M$. By a standard theorem of functional analysis, the weak* closed subspace $M$ of the dual space $B(H)$ is the dual of $M_*$. Thus $M$ is isometrically isomorphic to $A''$, and the weak* topology on $A''$ coincides with the weak* topology on $M$. 

10.5 Corollary. Let \( \rho \) be a representation of a C*-algebra \( \mathcal{A} \) on a Hilbert space \( \mathcal{N} \). Then there is a unique normal representation \( \tilde{\rho} \) of \( \mathcal{A}^\ast \) extending \( \rho \), and this takes \( \mathcal{A}^\ast \) onto \( \rho(\mathcal{A})^\ast \). Furthermore, there is a central projection \( P \) in \( \mathcal{A}^\ast \) such that the restriction of \( \tilde{\rho} \) to \( P\mathcal{A}^\ast \) is a \( * \)-isomorphism onto \( \rho(\mathcal{A})^\ast \).

Proof. Every representation \( \rho \) is the direct sum of cyclic representations \( \rho_\alpha \) (easy application of Zorn's lemma), and every cyclic representation \( (\rho_\alpha x_\alpha) \) equivalent to \( \pi_{f_\alpha} \), where \( f_\alpha \) is the state \( f_\alpha(A) = (\rho_\alpha(A)x_\alpha x_\alpha) \). One maps \( \mathcal{A}^\ast \) onto \( \pi_{f_\alpha}(\mathcal{A})^\ast \) by restriction to \( \mathcal{A} \), and this map is normal. Since \( \mathcal{A}^\ast \) is weakly closed, it maps onto \( \pi_{f_\alpha}(\mathcal{A})^\ast \). The direct sum of these maps is a normal representation \( \tilde{\rho} \) of \( \mathcal{A}^\ast \) onto \( \rho(\mathcal{A})^\ast \). But \( \mathcal{A} \) is weak\(^*\) dense in \( \mathcal{A}^\ast \), so this extension must be unique.

Let \( P \) be a maximal projection in \( J = \ker(\tilde{\rho}) \). This is the identity for \( J \) as this is a weak\(^*\) closed C*-algebra. Moreover, \( P \) is central in \( \mathcal{A}^\ast \); since if \( A \) belongs to \( \mathcal{A} \), then \( PA \) and \( AP \) are in \( J \). Thus \( PA = PAP = AP \). The restriction map of \( \tilde{\rho} \) to \( P\mathcal{A}^\ast \) is thus a \( * \)-isomorphism. \( \blacksquare \)

10.6 Theorem. Let \( \rho \) be a representation of a C*-algebra \( \mathcal{A} \) on a Hilbert space \( \mathcal{H} \). Let \( \delta \) be a derivation of \( \rho(\mathcal{A}) \) into a dual normal bimodule \( \mathcal{E} \). Then \( \delta \) is weak\(^*\) continuous, and thus extends to a derivation of \( \rho(\mathcal{A})^\ast \) into \( \mathcal{E} \) with the same norm.

Proof. Let \( \tilde{\rho} \) be the extension of \( \rho \) to a normal representation of \( \mathcal{A}^\ast \) onto \( \rho(\mathcal{A})^\ast \). By Corollary 10.5, there is a central projection \( P \) in \( \mathcal{A}^\ast \) such that the restriction \( \sigma \) of \( \tilde{\rho} \) to \( P\mathcal{A}^\ast \) is a \( * \)-isomorphism. Make \( \mathcal{E} \) into an \( \mathcal{A}^\ast \) bimodule by

\[
A \cdot E = \tilde{\rho}(A)E \quad \text{and} \quad E \cdot A = E\tilde{\rho}(A)
\]

for \( A \) in \( \mathcal{A}^\ast \) and \( E \) in \( \mathcal{E} \). Since \( \tilde{\rho} \) is normal, and \( \mathcal{E} \) is a dual normal \( \rho(\mathcal{A})^\ast \) bimodule, it becomes a dual normal \( \mathcal{A}^\ast \) bimodule.

Let \( \phi \) be a functional in \( \mathcal{E}^\ast \). By Theorem 10.3, \( \delta \) is continuous, so \( f(A) = \phi(\delta(\rho(A))) \) is a continuous functional (in \( \mathcal{A}^\ast \)). Thus \( f \) is weak\(^*\) continuous on \( \mathcal{A}^\ast \). Therefore, \( \delta \circ \rho \) is a normal map of \( \mathcal{A} \) into \( \mathcal{E} \). Thus it extends to a linear map \( \delta \) of \( \mathcal{A}^\ast \) onto \( \mathcal{E} \) which is weak\(^*\)-weak\(^*\) continuous. Since the unit ball of a Banach space is dense in the ball of its double dual, \( \| \delta \| = \| \delta \| \). Furthermore, \( \delta \) is a derivation. To see this, let \( A \) and \( B \) be elements of \( \mathcal{A}^\ast \), and choose nets \( A_\alpha \) and \( B_\beta \) in \( \mathcal{A} \) converging weak\(^*\) to \( A \) and \( B \). Then
\[ \tilde{\delta}(AB) = \lim \delta \circ \rho(A_\omega B_\omega) \]
\[ = \lim A_\omega \delta(\rho(B_\omega)) + \delta(\rho(A_\omega))B_\omega = A\tilde{\delta}(B)+\tilde{\delta}(A)B. \]

Also, \( \tilde{\delta}(P) = \tilde{\delta}(P) = \tilde{\rho}(P)\tilde{\delta}(P)+\tilde{\delta}(P)\tilde{\rho}(P) = 2\tilde{\delta}(P). \) Thus \( \tilde{\delta}(P) = 0. \)

Define a map \( \hat{\delta} \) of \( \rho(A)'' \) into \( \mathcal{E} \) by \( \hat{\delta}(X) = \tilde{\delta}(\sigma^{-1}(X)). \) This is a weak*-weak* continuous map since both \( \sigma^{-1} \) and \( \tilde{\delta} \) are normal, and it is easily seen to be a derivation. Furthermore, if \( A \) belong to \( A, \)
\[ \hat{\delta}(\rho(A)) = \hat{\delta}(\sigma^{-1}(\rho(A))) = \tilde{\delta}(PA) \]
\[ = \tilde{\delta}(P)\rho(A) + \tilde{\rho}(P)\tilde{\delta}(A) \]
\[ = \delta(\rho(A)). \]

So \( \hat{\delta} \) is an extension of \( \delta \) as desired.

\[ \textbf{10.7 Lemma.} \quad \text{Every derivation } \delta \text{ of a finite dimensional } C^*\text{-algebra is inner, and } \delta = \delta_E \text{ for } E \text{ in } \mathcal{E} \text{ with } \|E\| \leq \|\delta\|. \]

\textbf{Proof.} Let \( \mathcal{G} \) be a finite group of unitaries in the \( C^*\text{-algebra } \mathcal{A} \) as in section 8.2 so that \( \mathcal{A} \) is the span of \( \mathcal{G}. \) Let
\[ E = \frac{1}{|\mathcal{G}|} \sum_{U \in \mathcal{G}} \delta(U)U^* \]

Then if \( V \) belongs to \( \mathcal{G}, \)
\[ \delta_E(V) = EV - VE = \frac{1}{|\mathcal{G}|} \sum_{U \in \mathcal{G}} \delta(U)U^*V - V\delta(U)U^* \]
\[ = \frac{1}{|\mathcal{G}|} \sum_{U \in \mathcal{G}} (\delta(U)U^* - \delta(VU)VU^*)V + \delta(V) = \delta(V). \]

So \( \delta = \delta_E, \) and \( \|E\| \leq \max\|\delta(U)U^*\| \leq \|\delta\|. \)

\[ \textbf{10.8 Theorem.} \quad \text{Let } \mathcal{A} \text{ be an AF von Neumann algebra. Then every derivation } \delta \text{ of } \mathcal{A} \text{ into a dual normal bimodule is inner, and } \delta = \delta_E \text{ with } \|E\| \leq \|\delta\|. \]

\textbf{Proof.} Let \( \mathcal{A}_\alpha \) be an increasing net of finite dimensional subalgebras of \( \mathcal{A} \) whose union is weak* dense. By Theorem 10.3, \( \delta \) is bounded. By Lemma 10.7, for each \( \alpha \) there is an element \( E_\alpha \) in \( \mathcal{E} \) so that \( \delta | \mathcal{A}_\alpha = \delta | E_\alpha \) and \( \|E_\alpha\| \leq \|\delta\|. \) By the Banach-Alaoglu Theorem, the ball of radius \( \|\delta\| \) in \( \mathcal{E} \) is weak* compact. Hence there is a cofinal subnet \( \Lambda \) such that \( E = \omega^*- \lim \Lambda E_\lambda \) exists. For every \( \alpha, \) there is a \( \lambda \) in \( \Lambda \) so that \( \alpha \leq \lambda. \) Thus if \( \mu \geq \lambda, \) \( \delta_{E_\mu} | \mathcal{A}_\alpha = \delta | \mathcal{A}_\alpha. \) Hence \( \delta_{E_\mu} | \mathcal{A}_\alpha = \delta | \mathcal{A}_\alpha \) for every \( \alpha. \) By Theorem 10.6, \( \delta \) is weak* continuous (as is \( \delta_E, \) clearly) so \( \delta = \delta_E. \)
Now, we turn to the consideration of derivations into the compact operators. The main result will be very important for its applications to nest algebras. We begin with the abelian case.

10.9 Theorem. Let \( \mathcal{M} \) be an abelian von Neumann algebra. Every derivation \( \delta \) of \( \mathcal{M} \) into the compact operator \( K \) is inner, and \( \delta = \delta_K \) for some \( K \) in \( K \) with \( \|K\| \leq \|\delta\| \).

Proof. By considering \( \delta \) as a derivation into \( B(\mathcal{H}) \) which is a dual normal \( \mathcal{M} \)-module, one has by Theorem 10.8 that \( \delta = \delta_T \) for some \( T \) in \( B(\mathcal{H}) \). Let \( \Phi \) be an expectation onto \( \mathcal{M}' \) given by Theorem 8.3. Set \( K = T - \Phi(T) \). Clearly, \( \delta_K = \delta_T \). It suffices to prove that \( K \) is compact.

Suppose that \( \|K\|_e = \gamma \neq 0 \). Let \( P \) be a maximal chain of projections in \( \mathcal{M} \) such that \( \|PKP\|_e = \gamma \) for all \( P \) in \( P \). If \( P \) belongs to \( P \) and \( P = P_1 + P_2 \), then

\[
\gamma = \|PKP\|_e = \|P_1KP_1 + P_2KP_2 + P_1KP_2 + P_2KP_1\|_e \\
= \|P_1KP_1 + P_2KP_2 + P_1\delta(P_2) + P_2\delta(P_1)\|_e \quad (10.9.1) \\
= \|P_1KP_1 + P_2KP_2\|_e = \max\{\|P_1KP_1\|, \|P_2KP_2\|\}.
\]

Let \( P_0 = \inf\{P : P \in P\} \). If \( P_0 \) belongs to \( P \), then the computation (10.9.1) along shows that \( P_0 \) must be minimal in \( P \) (for otherwise some smaller projection also belongs to \( P \)). But if \( P_0 \) is minimal, then since \( P_0\Phi(T) = P_0TP_0 \),

\[
P_0KP_0 = P_0TP_0 - P_0\Phi(T)P_0 = 0.
\]

Thus, \( P_0 \) does not belong to \( P \). By equation (10.9.1),

\[
\|P(P - P_0)K(P - P_0)\| = \gamma \quad \text{for every} \quad P \quad \text{in} \quad P.
\]

Let \( P = \{P_\alpha\} \) ordered by itself in decreasing order. Since the norm is lower semi-continuous in the weak* topology,

\[
\gamma = \lim_{\alpha} \|(P_\alpha - P_0)K(P - P_0)\| = \lim_{\alpha} \|(P_\alpha - P_0)K(P - P_\alpha)\|.
\]

Hence one may choose a sequence \( \alpha_1 > \alpha_2 > \ldots \) such that \( Q_\alpha = P_{\alpha_k} - P_{\alpha_k+1} \) satisfies \( \|Q_\alpha KQ_\alpha\| > \gamma/2 \). By Theorem 8.3,

\[
Q_\alpha KQ_\alpha = Q_\alpha (K - \Phi(K))Q_\alpha
\]

belongs to the weak* closed convex hull of

\[
\{Q_\alpha(K - \Phi(K))Q_\alpha : U \in U(\mathcal{M})\} = \{Q_\alpha(U)U^*Q_\alpha : U \in U(\mathcal{M})\}.
\]

Choose a unitary \( U_\alpha \) in \( \mathcal{M} \) such that \( \|Q_\alpha(U_\alpha)Q_\alpha\| > \gamma/2 \). Now
\[ Q_k \delta(Q_k^{\perp}U_k)Q_k = Q_k \delta(Q_k^{\perp}U_kQ_k^{\perp})Q_k \]
\[ = Q_k Q_k^{\perp} \delta(U_k Q_k^{\perp}) + Q_k \delta(Q_k^{\perp})U_k Q_k^{\perp} Q_k = 0 \]

So \( \gamma / 2 < \| Q_k \delta(Q_k U_k)Q_k \| \). Let \( A = \sum_{k=1}^{\infty} Q_k U_k \). This belongs to \( \mathcal{M} \), but
\[ \| Q_k \delta(A)Q_k \| = \| Q_k \delta(Q_k U_k)Q_k + Q_k \delta(Q_k^{\perp} A Q_k^{\perp})Q_k \| \]
\[ = \| Q_k \delta(Q_k U_k)Q_k \| \geq \gamma / 2 \]

This contradicts the compactness of \( \delta(A) \). Thus \( K \) is compact.

Since \( K = K - \Phi(K) \), it belongs to the weak* closed convex hull of \( K - U K U^* = \delta(U) U^* \) and hence \( \| K \| \leq \| \delta \| \).

**10.10 Lemma.** Let \( \mathcal{A} \) be the algebra of all \( n \times n \) matrices with coefficients in an abelian von Neumann algebra \( \mathcal{M} \). \( \mathcal{A} = M_n \otimes \mathcal{M} \). Then every derivation \( \delta \) of \( \mathcal{A} \) into the compact operators is inner, and \( \delta = \delta_K \) with \( K \) in \( \mathcal{K} \) and \( \| K \| \leq \| \delta \| \).

**Proof.** Again by Theorem 10.8, it suffices to consider \( \delta = \delta_T \) for \( T \) in \( B(\mathcal{H}) \). By Lemma 10.7, the restriction of \( \delta \) to the \( n \times n \) matrices with scalar entries is inner, so equals \( \delta_C \) for some compact operator \( C \). Let \( \delta' = \delta_{T - C} \). Let \( E_{ij} \) be the standard matrix units of \( M_n \). Then for \( M \) in \( \mathcal{M} \),
\[ \delta'(E_{ij} M) = \delta'(E_{ij} (E_1 ME_1) E_{ij}) = E_{ij} \delta'(E_1 ME_1) E_{ij} \]
The derivation \( \delta'' \) obtained by restricting \( \delta' \) to the 1–1 entry is then a derivation into \( E_1 K E_1 \). By Theorem 10.8, \( \delta'' = \delta_L \) where \( L \) is compact. Let \( K = L^{(n)} \) be the direct sum of \( n \) copies of \( L \). One has
\[ \delta'(E_{ij} M) = E_{ij} (LM - ML) E_{ij} = (K E_{ij} M) - (E_{ij} M) K \]
So \( \delta' = \delta_K \) and thus \( \delta = \delta_{C+K} \). Replace \( C \) by \( K' = C + K - \Phi(C+K) \) where \( \Phi \) is any expectation onto \( \mathcal{A}' \) (Theorem 8.3). Then by the remark following Theorem 8.6, \( \Phi(C+K) \) is compact. Furthermore, \( K' \) belongs to the convex hull of \( \{ C + K - U(C+K) U^*: U \in U(\mathcal{A}) \} \) which equals \( \{ \delta(U) U^*: U \in U(\mathcal{A}) \} \). Hence \( \| K' \| \leq \| \delta \| \).

**10.11 Lemma.** Let \( \mathcal{A} = B(\mathcal{H}) \otimes \mathcal{M} \) be the algebra of all infinite matrices \( (A_{ij})_{i,j \in \mathbb{Z}} \) with coefficients in a von Neumann algebra \( \mathcal{M} \) which are bounded operators. Every derivation of \( \mathcal{A} \) into the compacts is inner, and \( \delta = \delta_K \) for \( K \) in \( \mathcal{K} \) with \( \| K \| \leq \| \delta \| \).

**Proof.** First note that
\[ \mathcal{A} = B(\mathcal{H}) \otimes \mathcal{M} \cong B(\mathcal{H} \otimes \mathcal{H}) \otimes \mathcal{M} \cong B(\mathcal{H}) \otimes (B(\mathcal{H}) \otimes \mathcal{M}) \]
so \( \mathcal{A} \) can be thought of as infinite matrices with coefficients in \( \mathcal{A} \). Let \( U \) be the bilateral shift of infinite multiplicity given by the matrix \( (\delta_{ij+1})_n \). Then \( \mathcal{U} = \{U^i\}^n \) is an abelian von Neumann algebra. By Theorem 10.9, \( \delta |U = \delta_K \) with \( K \) compact. Let \( \delta' = \delta - \delta_K \). For any operator \( \mathcal{A} \) in \( \mathcal{U} \cap \mathcal{A} = \{(A_{ij})_n: A_{ij} = A_{i+1,j+1} \in \mathcal{A}\} \)
\[
\delta'(A)U = \delta'(AU) - A\delta'(U) = \delta'(UA) = U\delta'(A).
\]
So \( \delta'(A) \) belongs to \( \mathcal{U} \cap K = \{0\} \). Hence \( \delta |\mathcal{U} \cap K = \delta_K \).

Now considering \( \mathcal{U} \) as a subalgebra of \( \mathcal{A} \), the algebra \( \mathcal{D} \) of diagonal matrices with entries in \( \mathcal{U} \) is an abelian von Neumann subalgebra of \( \mathcal{A} \) such that \( \mathcal{D} \) contains no non-zero compact operators. Again use Theorem 10.9 to obtain a compact operator \( C \) so that \( \delta' |\mathcal{D} = \delta_C \). Write \( \mathcal{C} = (C_{ij})_n \) and note that each \( C_{ij} \) is compact. The constant diagonal matrix \( (C_{ij})^{(\infty)} \) belongs to \( \mathcal{D} \cap \mathcal{U} \), so
\[
0 = \delta(U^{(\infty)}) = \delta_C(U^{(\infty)}) = (C_{ij}U - UC_{ij}) .
\]
Hence each \( C_{ij} \) belongs to \( \mathcal{U} \cap K = \{0\} \), whence \( C = 0 \).

This shows that \( \delta = \delta_K \) on the algebras \( \mathcal{U} \) and \( \mathcal{D} \). But these generate \( \mathcal{A} \) as a weak* closed algebra. So by Theorem 10.8, \( \delta = \delta_K \) on all of \( \mathcal{A} \). As \( K \) was obtained from \( \delta |\mathcal{U} \), one has \( ||K|| \leq ||\delta|\mathcal{U}|| \leq ||\delta||. \)

**10.12 Johnson-Parrott Theorem.** If \( \mathcal{A} \) is a type I von Neumann algebra, then every derivation \( \delta \) into \( K \) is inner, and \( \delta = \delta_K \) for \( K \) in \( K \) with \( ||K|| \leq ||\delta|| \).

**Proof.** We prove this theorem when \( \mathcal{A} \) is abelian. The general case is the same, but relies on the extension of Theorem 7.14 given in Exercise 7.3 to classify all type I von Neumann algebras. By that theorem, \( \mathcal{A} \) is unitarily equivalent to a direct sum \( \sum_{n=1}^{\infty} \oplus (M_n \otimes R_n) \oplus (H \otimes \mathcal{R}_\infty) \) where \( R_n \) are abelian von Neumann algebras. By theorem 10.9, the restriction of \( \delta \) to the centre \( \mathcal{A} \cap \mathcal{A}' \) has the form \( \delta_K \) where \( K \) is compact. Let \( \delta' = \delta - \delta_K \). Then \( \delta'(E_n \mathcal{A}) = E_n \delta'(\mathcal{A})E_n \) for every central projection \( E_n \), and in particular, \( \delta' \) can be restricted to each summand \( M_n \otimes R_n \).

By Lemmas 9.10 and 9.11, \( \delta' = \sum_{n=1}^{\infty} \delta K_n \oplus \delta K_\infty \) where each \( K_n \) is compact, and \( ||K_n|| \leq ||\delta' |M_n \otimes R_n|| \). Choose \( U_n \) unitary in \( M_n \otimes R_n \), \( 1 \leq n \leq \infty \) such that \( ||\delta K_n(U_n)|| \geq \frac{1}{2}||K_n|| \). Then \( U = \sum \oplus U_n \) belongs to \( \mathcal{A} \), and \( \delta(U) = \sum \oplus \delta K_n(U_n) \) is compact. Thus
\[
0 = \lim_{n \to \infty} 2 ||\delta K_n(U_n)|| \geq \lim_{n \to \infty} ||K_n||
\]
and hence \( K' = \sum_{n=1}^{\infty} K_n \oplus K_\infty \) is compact. So \( \delta = \delta_{K+K'} \).
Let $\Phi$ be the expectation of $B(\mathcal{K})$ onto $\mathcal{A}$ given in Theorem 8.3. Then $\delta = \delta_{K+K'} - \Phi(K+K') = \delta L$. As in the proof of Lemma 10.10, $L$ is compact and $\|L\| \leq \|\delta\|$. 

**Notes and Remarks.**

Sakai [1] proved that derivations of $C^*$-algebras into themselves are norm continuous. Kadison [1] showed that derivations of $C^*$-algebras into themselves are weak* continuous and hence extend to their weak* closures. Kadison [1] and Sakai [2] independently proved that every derivation of a von Neumann algebra into itself is inner. The generalizations Theorems 10.3 and 10.4 for modules are due to Ringrose [6] and the proofs given here are his. Theorem 10.4 is due to Grothendieck [1], Sherman [1] and Takeda [1]. Theorem 10.8 is considerably easier than the Kadison-Sakai Theorem. Note that one needs some condition such as weak closure, for $\delta_T$ is a derivation of the compact operators $K$ into itself for every bounded operator $T$. Theorems 10.9 - 10.12 are due to Johnson and Parrott [1]. They prove Theorem 10.12 for purely infinite von Neumann algebras as well. This was extended to all von Neumann algebras by Popa [1].

**Exercises.**

10.1 Show that there are no non-zero derivations of $C(X)$ into itself. 
*Hint.* Show $\delta(1) = 0$. Then if $\delta(f) = f'$ and $x \in X$, write $f - f(x) = f'_1 - f'_2$ with $f_i(x) = 0$. Compute $f'(x)$.

10.2 (i) Let $\delta$ be a derivation of a $C^*$-algebra $\mathcal{A}$ onto itself. Let $\alpha_t = \exp(t\delta)$. Show that $\alpha_t$ is a one parameter group of automorphisms such that $t \to \alpha_t$ is norm continuous for all $t$.

(ii) If $\alpha$ is an automorphism of $\mathcal{A}$ such that $\|\alpha - \text{id}\| < 1$, show that $\delta = \log \alpha$ is a derivation.

(iii) Let $t \to \alpha_t$ be a norm continuous, one parameter group of automorphisms, and let $\delta$ be its infinitesimal generator. So $\alpha_t = \exp(t\delta)$ for some bounded map $\delta$ of $\mathcal{A}$ into itself. Show that $\delta$ is a derivation.

10.3 Let $\mathcal{A}$ be a $C^*$-algebra containing the compact operators $K$, and let $\alpha$ be an $\ast$-automorphism of $\mathcal{A}$.

(i) Show that $\alpha$ maps $K$ onto itself.

(ii) Show that there is a unitary $U$ such that $\alpha(K) = UKU^*$ for all $K$ in $K$.

(iii) Prove that $\alpha(A) = UAU^*$ for all $A$ in $\mathcal{A}$.

10.4 (Johnson-Parrott) Let $\mathcal{A}$ be an AF von Neumann algebra, and let $\delta$ be a derivation of $\mathcal{A} + K$ into itself. Let $\Phi$ be an expectation of $B(\mathcal{K})$ onto $\mathcal{A}$.
(i) Show that \( \Phi \delta \mid \mathcal{A} \) is a derivation of \( \mathcal{A} \) onto itself.

(ii) Show that \( \delta - \Phi \delta \mid \mathcal{A} \) is a derivation of \( \mathcal{A} \) onto \( \mathcal{K} \).

(iii) Prove that \( \delta = \delta_T \) for some operator \( T \) in \( \mathcal{A} + \mathcal{A}' + \mathcal{K} \).
11. M-Ideals

In this section, a method is developed for computing the distance to certain ideals. The important applications to nest algebra will be given in the next chapter. The key idea is a Banach space notion introduced by Alfonse and Effros. A closed subspace $\mathcal{M}$ of a Banach space $\mathcal{X}$ is an $\mathcal{M}$-ideal if there is a linear projection

$$\eta : \mathcal{X}^* \to \mathcal{M}^\perp$$

of the dual space $\mathcal{X}^*$ onto the annihilator $\mathcal{M}^\perp$ of $\mathcal{M}$ in $\mathcal{X}^*$ such that for all $\Phi$ in $\mathcal{X}^*$,

$$\| \Phi \| = \| \eta \Phi \| + \| \Phi - \eta \Phi \| .$$

In this case, $\mathcal{M}^\perp$ is an $L$-summand of $\mathcal{X}^*$. The range $\mathcal{M}$ of $(1-\eta)$ is a complementary subspace of $\mathcal{M}^\perp$, and $\mathcal{X}^* = \mathcal{M}^\perp \oplus_{\ell_1} \mathcal{M}$, meaning that the norm on $\mathcal{X}^*$ is the $\ell_1$ sum of the norms on the two subspaces.

11.1 Lemma. Let $\mathcal{M}$ be an $\mathcal{M}$-ideal in $\mathcal{X}$. Then every $\phi$ in $\mathcal{M}^*$ has a unique Hahn-Banach extension $\tilde{\phi}$ in $\mathcal{X}^*$. When $\mathcal{M}^*$ is identified as a subspace of $\mathcal{X}^*$ in this way, one obtains a decomposition $\mathcal{X}^* = \mathcal{M}^* \oplus_{\ell_1} \mathcal{M}^\perp$ with $\| \tilde{\phi} + \psi \| = \| \phi \| + \| \psi \|$ for $\phi$ in $\mathcal{M}^*$ and $\psi$ in $\mathcal{M}^\perp$.

Proof. Let $\Phi$ be any Hahn-Banach extension of $\phi$ to $\mathcal{X}^*$. Then $\eta \Phi$ annihilates $\mathcal{M}$, so $\Phi - \eta \Phi$ is an extension of $\phi$. Furthermore

$$\| \phi \| \leq \| \Phi - \eta \Phi \| \leq \| \Phi - \eta \Phi \| + \| \eta \Phi \| = \| \Phi \| = \| \phi \| .$$

Thus $\eta \Phi = 0$. The most general extension of $\phi$ is $\Phi + \psi$ where $\psi$ belongs to $\mathcal{M}^\perp$. However, since $\eta(\Phi + \psi) = \psi$,

$$\| \Phi + \psi \| = \| \Phi \| + \| \psi \| = \| \phi \| + \| \psi \| .$$

So the only Hahn-Banach extension of $\phi$ is $\Phi$, which we denote by $\tilde{\phi}$. Identify $\mathcal{M}^*$ with $\{ \tilde{\phi} : \phi \in \mathcal{M}^* \}$.

Let $\eta$ be the projection onto $\mathcal{M}^\perp$. Suppose that $\eta \Phi = 0$. Then $\phi = \Phi | \mathcal{M}$ belongs to $\mathcal{M}^*$ and the above argument shows that $\Phi = \tilde{\phi}$. Thus $\mathcal{M}^* = \ker \eta$. For any $\Phi$ in $\mathcal{X}^*$, one has $\Phi = (\Phi - \eta \Phi) + \eta \Phi$ is a sum of an element of $\mathcal{M}^*$ and an element of $\mathcal{M}^\perp$ such that

$$\| \Phi \| = \| \Phi - \eta \Phi \| + \| \eta \Phi \| .$$

Furthermore, $\mathcal{M}^* \cap \mathcal{M}^\perp = \{0\}$. So this is a direct sum. $\blacksquare$
A basic and elementary property of $M$-ideals is that they are proximinal, meaning that for every $x$ in $X$, there is an $m$ in $M$ such that $\|x-m\| = \text{dist}(x,M).

11.2 Lemma. Let $M$ be an $M$-ideal in $X$. Let $y$ be a vector in $X$ such that $\text{dist}(y,M) = 1$ and $\|y\| = 1+r$, and let $\epsilon > 0$. Then there is an $m$ in $M$ with $\|m\| \leq r$ and $\|y-m\| < 1+\epsilon$.

Proof. Suppose, to the contrary, the set $S = \{y-m: \|m\| \leq r, m \in M\}$ is disjoint from the set $(1+\epsilon)D$ where $D$ is the open unit ball of $X$. By the Hahn-Banach Theorem, there is a non-zero linear functional $\Phi$ in $X^*$ so that

$$\sup \{\text{Re} \Phi(x): x \in (1+\epsilon)D\} \leq \inf \{\text{Re} \Phi(y-m): \|m\| \leq r, m \in M\} .$$

Evaluating these expressions yields

$$(1+\epsilon)\|\Phi\| \leq \text{Re} \Phi(y) - r \|\phi\| \|M\| .$$

Write $\Phi = \tilde{\phi} + \psi$, where $\phi = \Phi \mid M$ and $\psi = \eta \Phi$. Then

$$\text{Re} \Phi(y) = \text{Re}(\tilde{\phi}(y) + \psi(y)) \leq \|\tilde{\phi}\| \|y\| + \|\psi\| \text{dist}(y,M) .$$

Hence

$$(1+\epsilon)\|\phi\| \leq \|\tilde{\phi}\|(1+r) + \|\psi\| - r \|\tilde{\phi}\| = \|\Phi\| .$$

This contradiction establishes the claim. ■

11.3 Theorem. Let $M$ be an $M$-ideal in $X$. Then $M$ is proximinal in $X$.

Proof. Let $x_0$ belong to $X$, normalized so that $\text{dist}(x_0,M) = 1$. Fix $\epsilon > 0$. Choose $m_0$ in $M$ with $\|m_0\| \leq \|x_0\| - 1$ so that $\|x_0-m_0\| < 1+\epsilon/2$. Recursively, choose $m_j$ in $M$, $j \geq 1$ so that $\|m_j\| \leq \epsilon/2^j$ and $\|x_0-\sum_{j=0}^n m_j\| < 1+\epsilon/2^{n+1}$. Then

$$\sum_{j=0}^\infty \|m_j\| \leq \|x_0\| - 1 + \sum_{j=1}^\infty \frac{\epsilon}{2^j} = \|x_0\| - 1 + \epsilon .$$

Thus $m = \sum_{j=0}^\infty m_j$ belongs to $M$. Furthermore,

$$\|x_0-m\| = \lim_{n \to \infty} \sup \|x_0 - \sum_{j=0}^n m_j\| \leq 1 .$$

Hence $\|x_0-m\| = 1$. (Plus, $\|x_0-m\| + \|m\| < \|x_0\| + \epsilon$.) ■
The important examples of $M$-ideals are ideals of $C^*$-algebras. To prove this, we need the material on the double dual of $A$ from section 10.4.

11.4 Theorem. Every (closed, two sided) ideal of a $C^*$-algebra is an $M$-ideal.

Proof. Let $J$ be an ideal in $C^*$-algebra $A$. By Theorem 10.4, $A^{**}$ is a von Neumann algebra. The weak* closure of $J$ in $A^{**}$ in $J''$, and this is an ideal in $A^{**}$. Let $P$ be the largest projection in $J''$. For any $A$ in $A^{**}$, $PA$ and $AP$ belong to $J''$. So $PA = (PA)P = P(AP) = AP$. Thus $P$ is a central projection in $A^{**}$.

Define a mapping $\eta$ on $A^*$ by

$$(\eta \phi)(A) = \phi(P^\perp A).$$

Then since $P^\perp J'' = \{0\}$, $\eta \phi$ belongs to $J^\perp$. Conversely, if $\phi$ belongs to $J^\perp$, then $\phi$ annihilates $J''$. Thus

$$\phi(A) = \phi(A - PA) = \eta \phi(A).$$

Thus $\eta$ is a projection onto $J^\perp$. Furthermore, since $P$ is central, $A^{**}$ is the direct sum of $J''$ and $P^\perp A^{**}$. The functional $\eta \phi$ attains its norm on $P^\perp A^{**}$, and $(\phi - \eta \phi)(A) = \phi(PA)$ attains its norm on $J''$. So if $\phi$ belongs to $A^*$, choose $J$ in $J''$ and $A$ in $P^\perp A^{**}$ with $\|J\| = \|A\| = 1$ such that

$$\eta \phi(A) = \|\eta \phi\|$$

and $\phi - \eta \phi(J) = \|\phi - \eta \phi\|$.

Then $\|J + A\| = 1$, and

$$\|\phi\| \geq \phi(J + A) = \eta \phi(A) + (\phi - \eta \phi)(J)$$

$$= \|\eta \phi\| + \|\phi - \eta \phi\| \geq \|\phi\|.$$

Hence $J^*$ is an $L$-summand of $A^*$, and $J$ is an $M$-ideal. \hfill \Box

Although no use will be made of the converse to Theorem 11.4, we include a proof for completeness.

11.5 Theorem. Every $M$-ideal of a $C^*$-algebra is a two sided ideal.

Proof. Let $M$ be an $M$-ideal in a $C^*$-algebra $A$. Then $A^* \cong M^* \oplus_{l_1} M^\perp$ and $A^{**} \cong M^{**} \oplus_{l_\infty} M^{*\perp}$, where $M^{**}$ is identified with $M^{\perp\perp}$. By Theorem 10.4, $A^{**}$ can be represented as a von Neumann algebra containing $A$ which is the weak* closure of $A$. Moreover, every state on $A$ is a vector state in this universal representation. Let the identity $I$ of $A^{**}$ decompose as $P \oplus Q$.

Let $f$ be any state on $A$, decomposed as $f = f_1 \oplus f_2$. Then
\[ \| f \| = 1 = f(I) = f_1(I) + f_2(I) \leq \| f_1 \| + \| f_2 \| = \| f \|. \]

So \( h_i = \| f_i \|^{-1} f_i \) are states, \( i = 1, 2 \). Moreover,
\[ 1 = h_1(I) = h_1(P) + h_1(Q) = h_1(P) \]
and
\[ 1 = h_2(I) = h_2(P) + h_2(Q) = h_2(Q). \]

Hence \( f(P) = \| f_1 \| \) belongs to \([0, 1]\) for every state, and thus \( 0 \leq P \leq I \).

This also shows that every state is a convex combination of a state in \( M^* \)
and a state in \( M^\perp \); thus, together they span all of \( A^* \).

Now suppose the state \( f \) is given by \( f(A) = (Ax, x) \). For \( f \) in \( M^* \),
\[ 1 = f(P) = (Px, x) = \| P^* x \|^2. \]

Hence \( x \) is an eigenvector for \( P \), and \( Px = x \). Thus if \( A \) belongs to \( A^{**} \), one has
\[ f(A) = (Ax, x) = (APx, x) = (P^* x, x) = f(P^*). \]

Likewise, if \( f \) belongs to \( M^\perp \), then \( Qx = x \), whence \( Px = 0 \). So
\[ 0 = (APx, x) = (P^* x, x) = f(P^*). \]

Consequently, \( g(AP) = g(PA) \) for every functional \( g \) in \( A^* \). So \( P \) is central. Moreover, if \( A \) belongs to \( M^{**} \) and \( f \) belongs to \( M^\perp \),
\[ f(A) = 0 = f(AP). \]

So \( g(A) = g(AP) \) for all \( g \) in \( A^* \) and thus \( P \) is the identity for \( M^{**} \). In particular, \( P \) is a projection.

Hence \( M^{**} = PA^{**} \) and \( M^\perp = P^\perp A^{**} \) are ideals of \( A^{**} \). Therefore \( M = M^{**} \cap A \) is an ideal in \( A \).

Let \( M \) be a \( M \)-ideal in a Banach space \( X \). The \( M^* \)-topology on \( X \) is
the weakest topology such that for every for \( \phi \) in \( M^* \), \( \phi \) is continuous on \( X \). In particular, a net \( m_\alpha \) of elements of \( M \) converges \( M^* \) to \( x \) in \( X \) if and only if
\[ \lim_\alpha \phi(m_\alpha) = \phi(x) \]
for every \( \phi \) in \( M^* \). This topology is not in general Hausdorff. In the case
of an ideal \( J \) of a \( C^* \)-algebra \( A \), the \( J^* \)-topology is Hausdorff exactly when
\( J \) is essential, meaning that \( A J = 0 \) implies \( A = 0 \).

An important special case is the ideal of compact operators \( K \), which
is an \( M \)-ideal in \( B(\mathcal{H}) \). In this case, \( K^* \) is identified with \( C_1 \) by Theorem
1.13. So the \( K^* \)-topology is precisely the weak* topology by Theorem 1.15.
The main result of this chapter is the following:

11.8 **Theorem.** Let $\mathcal{M}$ be an $M$-ideal in a Banach space $X$. Suppose that $S$ is a subspace of $X$ such that $S \cap \mathcal{M}$ is $M^*$ dense in $S$. Then

i) $S \cap \mathcal{M}$ is an $M$-ideal in $S$. Furthermore, $S + \mathcal{M}$ is closed and the quotient maps

$$\sigma : S/S \cap \mathcal{M} \rightarrow S + \mathcal{M}/\mathcal{M}$$

and

$$\tau : \mathcal{M}/S \cap \mathcal{M} \rightarrow S + \mathcal{M}/S$$

are isometric.

ii) $S + \mathcal{M}/S$ is an $M$-ideal in $X/S$. Thus if $S$ is proximinal in $X$, so is $S + \mathcal{M}$.

**Proof.** Let $\eta$ be the $L$-projection of $X^*$ onto $M^\perp$. First, we show that $\eta S^\perp$ is contained in $S^\perp$. Let $\Phi$ belong to $S^\perp$, and let $s$ belong to $S$. Let $m_\alpha$ be a net in $S \cap \mathcal{M}$ converging $M^*$ to $s$. Then since $\Phi - \eta \Phi$ belongs to $M^*$,

$$\eta \Phi(s) = \Phi(s) - (\Phi - \eta \Phi)(s) = - \lim_\alpha (\Phi - \eta \Phi)(m_\alpha) = - \lim_\alpha \Phi - \eta \Phi(m_\alpha) = 0.$$  

Thus $\eta \Phi$ belongs to $S^\perp$. Therefore, $S^\perp$ splits as the $\ell^1$ direct sum

$$S^\perp = \eta S^\perp \oplus \ell_1(1-\eta)S^\perp$$

in $X^* = M^\perp \oplus_1 M^*$. Thus, $S^*$ splits as an $\ell^1$ direct sum

$$S^* \cong X^*/S^\perp \cong M^\perp/\eta S^\perp \oplus_1 M^*/(1-\eta)S^\perp.$$  

It also follows that

$$S^\perp + M^\perp = M^\perp \oplus \ell_1(1-\eta)S^\perp.$$  

So $S^\perp + M^\perp$ is closed. It is obviously contained in $(S \cap \mathcal{M})^\perp$. Conversely, suppose $\phi$ belongs to $(S \cap \mathcal{M})^\perp$. Then $\eta \phi$ belongs to $M^\perp$, and $\phi - \eta \phi$ belongs to $M^* \cap (S \cap \mathcal{M})^\perp$. As $S \cap \mathcal{M}$ is $M^*$ dense in $S$, it follows that $\phi - \eta \phi$ annihilates $S$. So $(S \cap \mathcal{M})^\perp = S^\perp + M^\perp$. Thus, thinking of $S \cap \mathcal{M}$ as a subspace of $S$, its annihilator in $S^*$ is

$$(S \cap \mathcal{M})^\perp/S^\perp \cong M^\perp/\eta S^\perp \oplus_1 0.$$  

This is an $L$-summand of $S^*$. Hence $S \cap \mathcal{M}$ is an $M$-ideal in $S$.

Next, to compute the quotient norms, let $s$ belong to $S$ and $\psi$ belong to $(S \cap \mathcal{M})^\perp$. So $\psi = \eta \psi \oplus (1-\eta)\psi$, and $(1-\eta)\psi$ annihilates $S$. Also, $\eta \psi$ is an arbitrary element of $M^\perp$. Hence
\[ \text{dist}(s, S \cap M) = \sup \{ \psi(s) : \psi \in (S \cap M)^\perp, \|\psi\| \leq 1 \} \]
\[ = \sup \{ \psi(s) \eta \psi : \psi \in M^\perp, \|\psi\| \leq 1 \} = \text{dist}(s, M). \]

Therefore, the natural map \( \sigma \) of \( S/S \cap M \) onto \( S+M/M \) is isometric. Consequently, \( S+M \) is complete and hence closed in \( X \).

Similarly, if \( m \) belongs to \( M \),
\[ \text{dist}(m, S \cap M) = \sup \{ \psi(m) : \psi \in (S \cap M)^\perp, \|\psi\| \leq 1 \} \]
\[ = \sup \{ (\psi-\eta\psi)(m) : \psi \in (S \cap M)^\perp, \|\psi\| \leq 1 \} \]
\[ = \sup \{ (\psi-\eta\psi)(m) : \psi \in S^\perp, \|\psi\| \leq 1 \} \]
\[ = \sup \{ \psi(m) : \psi \in S^\perp, \|\psi\| \leq 1 \} = \text{dist}(m, S). \]

So, the map of \( M/S \cap M \) onto \( S+M/S \) also isometric.

For part ii),
\[ (S+M)^\perp = M^\perp \cap S^\perp = \eta S^\perp \oplus \varepsilon_0. \]

But \( (X/S)^* \) is isomorphic to \( S^\perp = \eta S^\perp \oplus (1-\eta)S^\perp \). Thus \( (S+M/S)^\perp = (S+M)^\perp \) as a subset of \( S^\perp \) is an \( L \)-summand. So \( S+M/S \) is an \( M \)-ideal in \( X/S \). Now, suppose \( S \) is proximinal in \( X \). For \( x \) in \( X \), apply Lemma 11.3 to \( S+M/S \) and choose \( m \) in \( M \) so that
\[ \text{dist}(x-m, S) = \text{dist}(x, S+M). \]

Since \( S \) is proximinal, there is an \( s \) in \( S \) so that
\[ \|x-m-s\| = \text{dist}(x-m, S) = \text{dist}(x, S+M). \]

Hence \( S+M \) is proximinal.

\subsection*{11.7 Corollary.}
Let \( S \) be a weak* closed subspace of \( B (\mathcal{H}) \) such that \( S \cap K \) is weak* dense in \( S \). Then \( S+K \) is closed and the map \( \sigma \) of \( S/S \cap K \) onto \( S+K/K \) is isometric. Furthermore, \( S \cap K \) is proximinal in \( S \) and \( S+K \) is proximinal in \( B (\mathcal{H}) \).

\textbf{Proof.} It was observed that the \( K^* \) topology is the weak* topology. Every weak* closed subspace of \( B (\mathcal{H}) \) is proximinal. For if \( x \) belongs to \( B (\mathcal{H}) \), let \( s_n \) belong to \( S \) such that \( \|x-s_n\| \) converges to \( \text{dist}(x, S) \). Let \( s \) be any weak* cluster point of the sequence \( s_n \). Then by the lower semicontinuity of the norm,
\[ \|x-s\| = \limsup \|x-s_n\| = \text{dist}(x, S). \]

Now, apply Theorem 11.6. \hfill \blacksquare

In many cases of interest, the \( M^* \) density of \( S \cap M \) can be assured by the use of approximate identities. A \textit{left approximate identity} for an algebra \( B \) is a net \( \{ e_\lambda : \lambda \in \Lambda \} \) such that \( b = \lim_A e_\lambda b \) for every \( b \) in \( B \).
11.8 Lemma. Let $J$ be an ideal in a $C^*$-algebra $\mathcal{A}$. Suppose that $S$ is a (possibly non self-adjoint) subalgebra of $\mathcal{A}$ and that $S \cap J$ contains a bounded approximate identity for $J$. Then $S \cap J$ is $J^*$ dense in $S$.

Proof. Let $\{\varepsilon_\lambda : \lambda \in \Lambda\}$ be the bounded approximate identity. Let $P$ be any weak* limit point of this net in $\mathcal{M}$*. Then

$$Pj = \lim_{\Lambda} \varepsilon_\lambda j = j$$

for all $j$ in $J$. Thus $P$ is the identity on $J^*$, and hence it is the central support projection of $J^*$. Since $P$ is the unique limit point, $\varepsilon_\lambda$ converges weak* to $P$. Let $\eta$ be the $L$-projection of $\mathcal{A}$* onto $J^\perp$. If $s$ belongs to $S$ and $\psi$ belongs to $\mathcal{M}$*,

$$\lim_{\Lambda} \psi(\varepsilon_\lambda s) = \psi(\lim_{\Lambda} \varepsilon_\lambda s) = \psi(s) = \psi(s)\eta \psi(s) = \psi(s)$$

Thus $\varepsilon_\lambda s$ converges $J^*$ to $s$. But $S$ is an algebra and $J$ is an ideal, so $\varepsilon_\lambda s$ belongs to $J \cap S$. Thus $J \cap S$ is $J^*$ dense in $S$.

We conclude this section with a useful method for improving approximate identities in a given subspace of a $C^*$-algebra. First, we include a standard $C^*$-algebra fact.

11.9 Lemma. Let $\mathcal{A}$ be a $C^*$-algebra. Then $\mathcal{A}$ contains a two-sided approximate identity $\{\varepsilon_\lambda : \lambda \in \Lambda\}$ such that $0 \leq \varepsilon_\lambda \leq 1$. If $\mathcal{A}$ is separable, $\{\varepsilon_\lambda\}$ may be taken to be a sequence.

Proof. Let $\Lambda$ be the net of finite subsets of $\mathcal{A}$* ordered by inclusion. For $\lambda = \{a_1, \ldots, a_n\}$, let

$$\varepsilon_\lambda = f_n(a_1^2 + \ldots + a_n^2)$$

where $f_n$ is the continuous function

$$f_n(x) = \begin{cases} 
0 & x \leq 0 \\
n^2x & 0 \leq x \leq 1/n^2 \\
1 & x \geq 1/n^2 
\end{cases}$$

Since $f_n(0) = 0$, $\varepsilon_\lambda$ belongs to $\mathcal{A}$, and $0 \leq \varepsilon_\lambda \leq 1$. Furthermore, if one represents $\mathcal{A}$ on a Hilbert space $\mathcal{H}$, one sees that $\varepsilon_\lambda$ dominates the spectral projection $E_{\lambda}(t : |t| \geq 1/n)$. Hence

$$\|a_i - e_\lambda a_i\| \leq \|1 - e_\lambda\| \|E_{\lambda}[-1/n, 1/n]a_i\| \leq \frac{1}{n}$$

Thus $\varepsilon_\lambda a$ converges to $a$ for all self-adjoint elements of $\mathcal{A}$, and thus for all of $\mathcal{A}$. Taking adjoints yields that it is a right approximate identity as well.
If $\mathcal{A}$ is separable, let $\{a_n, n \geq 1\}$ be a dense subset of $\mathcal{A}_{a.e}$. Let $\lambda_n = \{a_1, ..., a_n\}$ and $e_n = e_{\lambda_n}$ constructed above. Then if $a$ belongs to $\mathcal{A}_{a.e}$ and $\epsilon > 0$, choose $i$ so that $\|a-a_i\| < \epsilon$ and an $n \geq i$ so that $n\epsilon > i$. Then

$$\|a-a_n\| = \|1-e_n\| \|a-a_i\| + \|(1-e_n)a_i\| < 2\epsilon.$$ 

So, as above, $e_n$ is a two sided approximate identity for $\mathcal{A}$.

**11.10 Lemma.** Let $\mathcal{A}$ be a separable $C^*$-algebra. Suppose that $\{b_k\}$ is a bounded left approximate identity for $\mathcal{A}$. Then there exist convex combinations $e_n$ of $\{b_k\}$ such that

$$\lim_{n \to \infty} \|e_n\| = \lim_{n \to \infty} \|1-e_n\| = 1$$

and $e_n$ is a two sided approximate identity for $\mathcal{A}$.

**Proof.** Let $f_j, j \geq 1$, be a fixed two sided approximate identity for $\mathcal{A}$ such that $0 \leq f_j \leq 1$ for all $j$. Let $C = \sup \|b_k\|$, and let $N$ be an integer. Choose an integer $M \geq C^2 N^2$. Let $j_1 = N$, and recursively choose $j_i$ and $k_i$, $1 \leq i \leq M$ such that

1) $\|f_{j_i} - b_{k_i} f_{j_i}\| < 1/N$.
2) $\|b_{k_i} - b_{k_{i+1}} f_{j_{i+1}}\| < 1/N$.
3) $\|f_{j_i} - f_{j_i} f_{j_{i+1}}\| < 1/M$.

This is possible because $k_i$ is chosen to satisfy 1) since $\{b_k\}$ is an approximate identity. Then $j_{i+1}$ is chosen to satisfy 2) and 3) since $\{f_j\}$ is an approximate identity. Define

$$E_N = \frac{1}{M} \sum_{i=1}^{M} b_{k_i} \quad \text{and} \quad h_N = \frac{1}{M} \sum_{i=1}^{M} f_{j_i}.$$ 

It is routine to verify that $h_N$ is a two sided approximate identity with $0 \leq h_N \leq 1$. Now compute

$$\|e_N - h_N\| = \| \frac{1}{M} \sum_{i=1}^{M} b_{k_i} - f_{j_i}\|$$

$$= \| \frac{1}{M} \sum_{i=1}^{M} (b_{k_i} - b_{k_{i+1}} f_{j_{i+1}} + b_{k_{i+1}} (f_{j_{i+1}} - f_{j_i}) + (b_{k_i} f_{j_i} - f_{j_i})\|$$

$$\leq \frac{2}{N} + \| \frac{1}{M} \sum_{i=1}^{M} b_{k_i} \Delta_i\|$$

where $\Delta_i = f_{j_{i+1}} - f_{j_i}$. When $|i-j| \geq 2$, one has by 3) that

$$\|\Delta_i \Delta_j\| \leq 4/M.$$ 

Split the sum into two sums over the even and odd terms respectively.
\[ \left\| \frac{1}{M} \sum_{i \text{ even}} b_k \Delta_i \right\|^2 = \left\| \frac{1}{M^2} \sum_{i=1}^{m/2} \sum_{j=1}^{m/2} b_{k_{ij}} \Delta_{ik} \Delta_{ij}^* \right\| \leq \frac{1}{M^2} \left( \sum_{i=1}^{M/2} \left\| b_{k_i} \Delta_{i} \right\|^2 + \frac{M^2}{4} \cdot C^2 \cdot \frac{4}{M} \right) \leq \frac{1}{M^2} \left( \frac{M}{2} \cdot C^2 + M \cdot C^2 \right) = \frac{3C^2}{2M} < \frac{3}{2N^2}. \]

The sum over the odd terms is treated in the same way. Thus
\[ \left\| \frac{1}{M} \sum_{i=1}^{M} b_k \Delta_i \right\| \leq 2 \left( \frac{3}{2} \right)^{i/\sqrt{N}} / N < 3/\sqrt{N}. \]

Hence \( \|e_N-h_N\| < 5/N \), from which it follows that \( e_N \) is also a two sided approximate identity with
\[ \lim_{n \to \infty} \|e_n\| = \lim_{N \to \infty} \|1-e_N\| = 1. \]

By construction, \( e_N \) is in the convex hull of \( \{b_k\} \).

11.11 Proposition. Let \( A \) be a \( C^* \)-algebra with an ideal \( J \). Let \( S \) be a subalgebra of \( A \) such that \( S \cap J \) contains an approximate identity \( e_n \), satisfying
\[ \lim_{n \to \infty} \|e_n\| = \lim_{n \to \infty} \|1-e_n\| = 1. \]

Then for any \( a \) in \( A \),
\[ \text{dist}(a, S+J) = \lim_{n \to \infty} \text{dist}(a-e_n, S) = \lim_{n \to \infty} \text{dist}(a-e_n, a, S) . \]

Proof. Since \( ae_n \) belongs to \( J \), \( \text{dist}(a-ae_n, S) \geq \text{dist}(a, S+J) \). So \( \text{dist}(a, S+J) \leq \lim_{n \to \infty} \text{dist}(a-ae_n, S) \). Conversely, if \( J \) belongs to \( J \) and \( s \) is in \( S \), then
\[ (a-s-j)(1-e_n) = (a-ae_n)+(s-se_n)+(j-jc_n). \]
Since \( \|j-jc_n\| \) tends to zero and \( (s-se_n) \) belongs to \( s \),
\[ \lim_{n \to \infty} \text{dist}(a-ae_n, S) \leq \lim_{n \to \infty} \|a-s-j\| \|1-e_n\| = \|a-s-j\| . \]
Taking the infimum over all \( s \) and \( j \) yields the desired equality.

The "left" version is proved in the same manner.

Notes and Remarks.

\( M \)-ideals were introduced by Alfsen and Effros [1]. They say that a subspace \( M \) of a Banach space \( X \) has the \( n \)-ball property if given \( n \) open balls \( B_1, \ldots, B_n \) such that \( \bigcap_{i=1}^n B_i \neq \emptyset \) and \( B_i \cap M \neq \emptyset \) for \( 1 \leq i \leq n \), then
\[ M \cap \bigcap_{i=1}^{n} B_i \neq \emptyset. \] Their main result is

**Theorem.** Let \( M \) be a subspace of a Banach space \( X \). The following are equivalent

1. \( M \) is an \( M \)-ideal.
2. \( M \) has the \( n \)-ball property for all \( n \).
3. \( M \) has the 3-ball property.

Theorem 11.3 is due to them, but the simple proof given here is taken from Gamelin, Marshall, Younis and Zame [1]. Theorems 11.4 and 11.5 are due to Alfonso and Effros in the real case, and to Smith and Ward [1] in the complex case.

The remainder of this chapter is taken from Davidson and Power [2] except for the standard result Lemma 11.9 on approximate identities in \( C^* \)-algebras. This paper also contains a constructive approach generalizing a method due to Axler, Berg, Jewell and Shields [1].

**Exercises.**

11.1 A subspace \( M \) of a Banach space has the strong \( n \)-ball property if given \( n \) open balls \( B_1, \ldots, B_n \) such that \( \bigcap_{i=1}^{n} B_i \neq \emptyset \) and \( B_i \cap M \neq \emptyset \),

1 \leq i \leq n, then \( M \cap \bigcap_{i=1}^{n} B_i \neq \emptyset. \)

(i) Show that the strong \( n \) ball property implies the \( n \) ball property, which in turn implies the strong \((n-1)\) ball property.

(ii) Show that the 2 ball property implies that \( M \) is proximinal.

(iii) (Holmes, Scranton, Ward) Suppose that \( M \) has the strong two ball property. Show that for each \( x \notin M \), the set of closest approximants in \( M \) spans all of \( M \).

Hint: Say \( \text{dist}(x, M) = 1 \). For each unit vector \( m \) in \( M \), consider \( B_1(x) \) and \( B_1(x+m/2) \).

11.2 (i) Use approximate identities to show that if \( A \) is a (two sided) ideal in a \( C^* \)-algebra \( B \), and \( B \) is an ideal in a \( C^* \)-algebra \( C \), then \( A \) is an ideal in \( C \).

(ii) Show that if \( M \) is an \( M \)-ideal in \( X \), and \( X \) is an \( M \)-ideal in \( Y \), then \( M \) is an \( M \)-ideal in \( Y \).

11.3 (Davidson-Power) Let \( J \) be an ideal in a \( C^* \)-algebra \( A \). The \( J \)-weak topology is the weakest topology in \( A \) such that \( \phi(AJ) \) is continuous for every \( J \) in \( J \) and \( \phi \) in \( J' \). Similarly, the \( J \)-strong (and \( J \)-strong*) are the weakest topologies such that \( A \to AJ \) (and also \( A \to JA \)) are continuous for all \( J \) in \( J \).
(i) Think of \( \mathcal{A} \) acting on \( J \) by left multiplication, and is thus a subalgebra of \( B(J) \). Show that the \( J \)-weak, strong, strong* topologies are induced by the corresponding operator topologies. Hence deduce that the \( J \)-weak, \( J \)-strong and \( J \)-strong* topologies have the same closed convex sets.

(ii) Show that the \( J \)-weak topology coincides with the \( J^* \) topology.

Hint: Use the Cohen factorization theorem to show that every \( \psi \) in \( J^* \) has the form \( \psi(X) = \phi(XJ) \) for some \( J \) in \( J \), \( \phi \) in \( J^* \).

11.4 (Davidson-Power) Let \( M, X \) and \( S \) be as in theorem 11.5. Define a map \( \tau \) of \( S \) into \( M^{**} \) by \( \tau(S)(\phi) = \phi(S) \).

(i) Show that \( \tau(S) \cap M \) is weak* dense in \( \tau(S) \), and hence show that \( \tau(S) \) is contained in \( (\tau(S) \cap M)^* \).

(ii) Deduce that the unit ball of \( \tau(S) \cap M \) is weak* dense in the ball of \( \tau(S) \), and hence that the ball of \( S \cap M \) is \( M^* \) dense in ball of \( S \).

(iii) If \( X \) is a \( C^* \)-algebra and \( M \) is an ideal show that the ball of \( S \cap M \) is \( M \)-strong* dense in the ball of \( S \).

11.5 (Axler-Berg-Jewell-Shields)

(i) Let \( K \) be compact, and let \( B_n \) be a sequence of operators converging strong* to 0. Show that for \( \varepsilon > 0 \), there is an integer \( n_0 \) so that \( n \geq n_0 \) implies \( \|K + B_n\| < \max\{\|K\|,\|B_n\|\} + \varepsilon \).

(ii) Let \( B_n \) be as above, and let \( A \) be an operator. Given \( \varepsilon > 0 \), find \( n_0 \) so that \( n \geq n_0 \) implies

\[
\|A + B_n\| \leq \max\{\|A\|,\|A\|,\|A\|,\|B_n\|\} + \varepsilon
\]

Hint: Write \( A = A_0 + K \) where \( \|A_0\| = \|A\|, \|K\| = \|A\| - \|A\|, \) and \( K \) is compact.

(iii) Let \( A \) be the weak* limit of a sequence \( K_n \) of compact operators. Let \( \epsilon_n = C^*(K_n) \) and \( C = \sup\|B_n\| \). Let \( \epsilon_n = C^*(K_n) = C^*(C + 1) \epsilon_{k+1} \). Show that one may choose integers \( n_k \) by induction so that \( \|\sum_{k=1}^m \epsilon_k B_{n_k}\| < \|A\| \) for all \( m \geq 1 \).

(Hint: Apply (ii) to the partial sum and appropriate \( \epsilon \)).

(iv) With \( A, K_n \) as above, find a convex combination \( K \) of \( \{K_n, n \geq 1\} \) so that \( \|A - K\| = \|A\| \).
12. Quasitriangular Algebras

An operator $T$ in $B(K)$ is *quasitriangular* if there is an increasing sequence $P_n$ of finite rank projections such that $\lim_{n \to \infty} \| P_n^* T P_n \| = 0$. This notion was used in Theorem 3.1 to obtain invariant subspaces for compact operators. It is easy to find a compact perturbation of $T$ which is upper triangular with respect to some basis. In fact, it follows from Theorem 12.2 below that $T$ belongs to $\mathcal{T}(P) + K$ where $P$ is the nest $\{ P_n \}$, $n \geq 1$. It is convenient to consider the more general family of algebras $\mathcal{Q} \mathcal{T}(K) = \mathcal{T}(K) + K$ for an arbitrary nest. This will be called the quasitriangular algebra of $K$. However, $\mathcal{Q} \mathcal{T}(K)$ need not consist of quasitriangular operators. Precisely which kinds of operators occur in $\mathcal{Q} \mathcal{T}(K)$ will be surveyed in chapter 21.

12.1 Theorem. $\mathcal{Q} \mathcal{T}(K)$ is norm closed. For each $T$ in $\mathcal{T}(K)$, there is a compact operator $K$ in $\mathcal{T}(K) \cap K$ such that $\| T - K \| = \| T \|$. Hence the quotient map $\pi$ of $\mathcal{T}(K)/\mathcal{T}(K) \cap K$ onto $\mathcal{Q} \mathcal{T}(K)/K$ is isometric. Also,

$$\text{dist}(K, \mathcal{T}(K) \cap K) = \text{dist}(K, \mathcal{T}(K))$$

for all $K$ compact.

Proof. By the Erdos Density Theorem 3.11, $\mathcal{T}(K) \cap K$ is weak* dense in $\mathcal{T}(K)$. Thus by Theorem 11.5 and Corollary 11.6, $\mathcal{T}(K) \cap K$ is an $M$-ideal in $\mathcal{T}(K)$ and the quotient maps $\pi$ defined above and $\sigma$ taking $K/\mathcal{T}(K) \cap K$ onto $\mathcal{Q} \mathcal{T}(K)/\mathcal{T}(K)$ are isometric. By Theorem 11.3, $\mathcal{T}(K) \cap K$ is proximinal in $\mathcal{T}(K)$. Thus there is a $K$ in $K$ such that

$$\| T - K \| = \text{dist}(T, \mathcal{T}(K) \cap K) = \text{dist}(T, K) = \| T \|_e.$$ 

The other estimate is a restatement of the fact that $\sigma$ is isometric.

12.2 Theorem. Let $P$ be a nest $\{ P_n \}$ where $P_n$ is an increasing sequence of finite rank projections. Then for $A$ in $B(K)$,

$$\text{dist}(A, \mathcal{Q} \mathcal{T}(P)) = \limsup_{n \to \infty} \| P_n^* A P_n \|.$$ 

Consequently, $\mathcal{Q} \mathcal{T}(P)$ consists of all operators which are quasitriangular with respect to the sequence $\{ P_n \}$.

Proof. $\mathcal{T}(P) \cap K$ contains the sequence $\{ P_n \}$ which is a two sided approximate identity for $K$ satisfying $\| P_n \| = \| P_n^* \| = 1$. Hence by
Proposition 11.10,
\[ \text{dist}(A, Q \tau(P)) = \lim_{n \to \infty} \text{sup } \text{dist}(P_n^\perp A, \tau(P)) . \]

But by Arveson’s distance formula (Theorem 9.5),
\[ \text{dist}(P_n^\perp A, \tau(\mathcal{H})) = \sup_{k \geq 1} \| P_k^\perp (P_n^\perp A) P_k \| = \sup_{k \geq n} \| P_n^\perp A P_k \| . \]

This is decreasing in \( n \), thus
\[ \text{dist}(A, Q \tau(P)) = \lim_{n \to \infty} \| P_n^\perp A P_n \| . \]

If this limit is zero, then \( A \) belongs to \( Q \tau(P) \) by Theorem 12.1. ■

This can be generalized in a certain sense, but Proposition 12.3 below is not particularly satisfying. A better result is Theorem 12.6.

12.3 Proposition. Let \( \mathcal{N} \) be a nest on a separable space. There is an approximate identity \( E_n \) for \( \mathcal{K} \) in \( \tau(\mathcal{N}) \cap \mathcal{K} \) such that for all \( A \) in \( \mathcal{B}(\mathcal{H}) \),
\[ \text{dist}(A, Q \tau(\mathcal{H})) = \lim_{n \to \infty} \sup_{N \in \mathcal{N}} \| P(N)^\perp A (I - E_n) P(N) \| . \]

Proof. By the Erdos Density Theorem 3.11, \( \tau(\mathcal{H}) \cap \mathcal{K} \) contains a bounded approximate identity for \( \mathcal{K} \). Thus by Lemma 11.9, it contains an approximate identity \( E_n \) such that
\[ \lim_{n \to \infty} \| E_n \| = \lim_{n \to \infty} \| I - E_n \| = 1 . \]

So by Proposition 11.10 and the distance formula Theorem 9.5,
\[ \text{dist}(A, Q \tau(\mathcal{H})) = \lim_{n \to \infty} \text{dist}(A(I - E_n), \tau(\mathcal{H})) = \lim_{n \to \infty} \sup_{N \in \mathcal{N}} \| P(N)^\perp A(I - E_n) P(N) \| . \] ■

12.4 Let \( \mathcal{N} \) be a nest. For \( A \) in \( \mathcal{B}(\mathcal{H}) \), define a function \( \Phi_A \) on \( \mathcal{N} \) by \( \Phi_A(N) = P(N)^\perp A P(N) \). This map is continuous in a certain sense. For if \( N_\alpha \) converges to \( N \) in the order topology, then \( P(N_\alpha) \) converges to \( P(N) \) in the strong operator topology by Proposition 2.13. Thus \( \Phi_A(N_\alpha) \) converges to \( \Phi_A(N) \) in the strong operator topology. Likewise, \( \Phi_A(N_\alpha)^* \) converges strongly to \( \Phi_A(N)^* \). So \( \Phi_A \) is a strong* continuous, bounded function. The set \( C_{\mathcal{N}}(\mathcal{N}, \mathcal{B}(\mathcal{H})) \) is the space of all bounded, strong* continuous functions of \( \mathcal{N} \) into \( \mathcal{B}(\mathcal{H}) \) endowed with the norm \( \| \Phi \| = \sup \| \Phi(N) \| . \)
This is a $C^*$-algebra under point-wise multiplication because multiplication is jointly continuous in the strong* topology on bounded sets. In this formulation, Arveson's distance formula becomes

$$\text{dist}(A, T(\mathcal{N})) = \|\Phi_A\|.$$  

Let $C_n(\mathcal{N}, K)$ denote the subalgebra of norm continuous functions into the compact operators. This is in fact a two sided ideal in $C_\mathcal{B}(\mathcal{N}, B(\mathcal{N}))$. Clearly, the product of a compact valued function with a bounded one is compact valued. So it suffices to show that if a bounded net $A_\alpha$ converges to $A$ strong* and $K_\alpha$ converges to $K$ in norm, then $A_\alpha K_\alpha$ converges to $AK$ and $K_\alpha A_\alpha$ converges to $KA$. But

$$\|A_\alpha K_\alpha - AK\| \leq \|A_\alpha\| \|K_\alpha - K\| + \|(A_\alpha - A)K\|.$$  

By Proposition 1.18, the second term tends to zero, and the first clearly does. The multiplication on the right is dealt with by taking adjoints.

12.5 Theorem. A belongs to $Q \tau(\mathcal{N})$ if and only if $\Phi_A$ belongs to $C_n(\mathcal{N}, K)$.

Proof. If $A = T + K$ where $T$ belongs to $\tau(\mathcal{N})$ and $K$ is compact, then $\Phi_A(K) = \Phi_K(K) = P(N)^{-1}Kp(N)$. The constant map $\Phi(N) = K$ is in $C_n(\mathcal{N})$, and $\Pi(N) = P(N)$ belongs to $C_\mathcal{B}(\mathcal{N})$. Since $C_n(\mathcal{N})$ is an ideal in $C_\mathcal{B}(\mathcal{N})$, $\Phi_A = \Pi^{-1} \Phi \Pi$ also belongs to $C_n(\mathcal{N})$. On the other hand, suppose $\Phi_A$ belongs to $C_n(\mathcal{N}, K)$. Let $\epsilon > 0$, and use the continuity of $\Phi_A$ to select a finite subnest $\mathcal{F}:\{0\} = N_0 < N_1 < ... < N_n = \mathcal{N}$ such that

$$\|\Phi_A(N) - \Phi_A(N_j)\| < \epsilon \text{ for } N_{j-1} < N \leq N_j, 1 \leq j \leq n.$$  

Let $P_j = P(N_j)$ and define the compact operator $K = \sum_{j=1}^{n} P_j A(P_j - P_{j-1}) = \sum_{j=1}^{n} \Phi_A(N_j)P_j$. Thus

$$A - K = \sum_{j=1}^{n} P_j A(P_j - P_{j-1}).$$  

So if $N_{j-1} < N \leq N_j$ and $P = P(N)$, then $P^{-1}P_i = 0$ for $i < j$ and $(P_j - P_{j-1})P = 0$ for $i > j$. Hence

$$\Phi_{A - K}(N) = \Phi_A(N)P = (P_j - P_{j-1})\Phi_A(N)(P_j - P_{j-1}).$$  

But $(P_j - P_{j-1})\Phi_A(N_j) = 0$, hence
\[ \| \Phi_{A-K}(N) \| = \| (P_j-P_{j-1})(\Phi_A(N)-\Phi_A(N_j))(P_j-P_{j-1}) \| < \epsilon \]

By the distance formula, \( \text{dist}(A-K, T(N)) \leq \epsilon \). But \( \epsilon > 0 \) is arbitrary, and thus \( A \) belongs to the closure of \( T(N) + K \). By Theorem 12.1, \( A \) belongs to \( Q \circ T(N) \).

Now this result is combined with the results of Chapter 11 to obtain a distance formula. For \( \Phi \) in \( C_\mathcal{N}(\mathcal{N}, K) \), let
\[ \| \Phi \|_e = \text{dist}(\Phi, C_\mathcal{N}(\mathcal{N}, K)) \]

12.6 Theorem. Let \( \mathcal{N} \) be a nest, and let \( A \) belong to \( B(\mathcal{N}) \). Then
\[ \text{dist}(A, Q \circ T(N)) = \| \Phi_A \|_e \]

**Proof.** Let \( S \) consist of \( \{ \Phi_A : A \in B(\mathcal{N}) \} \). From the distance formula, one has that \( S \) is isometrically isomorphic to \( B(\mathcal{N})/T(N) \) and thus it is closed. The subset \( \{ \Phi_A : A \in Q \circ T(N) \} \) is the intersection \( S \cap C_\mathcal{N}(\mathcal{N}, K) \) by Theorem 12.5. So
\[ \text{dist}(A, Q \circ T(N)) = \inf(\| \Phi_{A-K} \| : K \in K) = \text{dist}(\Phi_A, S \cap C_\mathcal{N}(\mathcal{N}, K)) \]

We wish to show that \( S \cap C_\mathcal{N}(\mathcal{N}, K) \) is \( C_\mathcal{N}(\mathcal{N}, K)^* \) dense in \( S \). By the Erdos Density Theorem 3.11, there is a bounded approximate identity \( E_\alpha \) for \( K \) in \( T(N) \). Let \( \Psi_\alpha \) be the function on \( \mathcal{N} \) with constant value \( E_\alpha \). If \( \Phi \) belongs to \( C_\mathcal{N}(\mathcal{N}, K) \), then the range of \( \Phi \) is the continuous image of a compact set, and thus is compact. Hence \( \Phi(N)E_\alpha \) converges to \( \Phi(N) \) uniformly on \( \mathcal{N} \). So \( \Psi_\alpha \) is a bounded approximate identity for \( C_\mathcal{N}(\mathcal{N}, K) \). From the proof of Lemma 11.7, it follows that \( \Phi \Psi_\alpha \) converges to \( \Phi \) in the \( C_\mathcal{N}(\mathcal{N}, K)^* \) topology for every \( \Phi \) in \( C_\mathcal{N}(\mathcal{N}, K) \). Now let \( \Pi \) be the projection in \( C_\mathcal{N}(\mathcal{N}, K) \) given by \( \Pi(N) = P(N) \). For each \( \phi \) in \( C_\mathcal{N}(\mathcal{N}, K)^* \), define another functional \( \phi_\Pi(\Phi) = \phi(\Phi \Pi) \). Then
\[ \lim_\alpha \phi_\alpha(\Phi \Psi_\alpha \Pi) = \lim_\alpha \phi_\Pi(\Phi \Psi_\alpha) = \phi_\Pi(\Phi) = \phi(\Phi \Pi) \]

Hence \( \Phi \Psi_\alpha \Pi \) converges \( C_\mathcal{N}(\mathcal{N}, K)^* \) to \( \Phi \Pi \). For \( \Phi_A \) in \( S \), \( \Phi_A = \Phi_A \Pi \) and
\[ \Phi_A \Psi_\alpha \Pi(N) = P(N) \Pi A \Pi P(N)E_\alpha P(N) = P(N) \Pi A \Pi E_\alpha P(N) = \Phi_{AE_\alpha}(N) \]

Thus, \( S \cap C_\mathcal{N}(\mathcal{N}, K) \) is \( C_\mathcal{N}(\mathcal{N}, K)^* \) dense in \( S \).

By Theorem 11.5, one now has
\[
dist(A, Q \mathcal{T}(\mathcal{N})) = \dist(\Phi_A, \mathcal{S} \cap C_n(\mathcal{M}, \mathcal{K})) \\
= \dist(\Phi_A, C_n(\mathcal{M}, \mathcal{K})) = \| \Phi_A \|_e.
\]

Note that \(\| \Phi_A \|_e\) is NOT just \(\sup \| P(N) - AP(N) \|_e\). For example, in the special case of Theorem 12.2, \(\Phi_A\) is always compact valued. It may however fail to be continuous at the end point \(\mathcal{N}\). That is precisely what is measured by \(\lim_{n \to \infty} \| P_n - AP_n \|\).

12.7. Now we turn to the major problem solved in this section: When are \(Q \mathcal{T}(\mathcal{M})\) and \(Q \mathcal{T}(\mathcal{N})\) equal? One simple way this can occur is to take a finite dimensional subspace \(R\) such that \(P(R)\) belongs to \(\mathcal{N}'\). The nest \(\mathcal{N}' = \{\{0\}, R \mathcal{R} N : N \in \mathcal{N}\}\) is another nest; and such a nest will be called a finite perturbation of \(\mathcal{N}\). For any operator \(T\) in either \(\mathcal{T}(\mathcal{M})\) or \(\mathcal{T}(\mathcal{N}')\), the compact perturbation \(P(R)^{-1}TP(R)^{-1}\) belongs to both \(\mathcal{T}(\mathcal{M})\) and \(\mathcal{T}(\mathcal{N}')\). Thus \(Q \mathcal{T}(\mathcal{N}') = Q \mathcal{T}(\mathcal{N})\). An order isomorphism \(\theta\) of \(\mathcal{N}\) onto \(\mathcal{M}\) preserves dimension if \(\dim \theta(N) = \dim N' / N\) for all \(N < N'\) in \(\mathcal{N}\). Two nests \(\mathcal{N}\) and \(\mathcal{M}\) will be called compactly perturbed if there are finite perturbations \(\mathcal{N}'\) and \(\mathcal{M}'\) and a dimension preserving order isomorphism \(\theta\) of \(\mathcal{N}'\) onto \(\mathcal{M}'\) such that \(\theta - \text{id}(N) = P(\theta(N)) - P(N)\) is continuous and compact valued (i.e. belongs to \(C_n(\mathcal{M}, \mathcal{K})\)).

Two nests \(\mathcal{N}\) and \(\mathcal{M}\) are similar if there is an invertible operator \(S\) such that \(S\mathcal{N} = \{SN : N \in \mathcal{N}\}\) equals \(\mathcal{M}\). A similarity induces an order isomorphism \(\theta_S\) of \(\mathcal{N}\) onto \(\mathcal{M}\). One has the identity
\[
\mathcal{T}(S\mathcal{N}) = S \mathcal{T}(\mathcal{N})S^{-1}.
\]
For if \(T\) belongs to \(\mathcal{T}(\mathcal{N})\), and \(N\) belongs to \(\mathcal{N}\),
\[
STS^{-1}(SN) = ST(N) \subseteq SN.
\]
So \(STS^{-1}\) belongs to \(\mathcal{T}(\mathcal{M})\). And the reverse inclusion follows by reversing the roles of \(\mathcal{N}\) and \(\mathcal{M}\). If \(S\) has the form \(I + K\) with \(K\) compact, then clearly \(Q \mathcal{T}(S\mathcal{N}) = Q \mathcal{T}(\mathcal{N})\).

Two nests \(\mathcal{N}\) and \(\mathcal{M}\) approximately unitarily equivalent if there is a sequence \(U_n\) of unitaries and an order isomorphism \(\theta\) of \(\mathcal{N}\) onto \(\mathcal{M}\) such that \(\Phi_n(N) = P(U_nN) - P(\theta(N))\) is compact valued and converges uniformly to 0. If all the \(U_n\) are compact perturbations of the identity, it will be shown that \(Q \mathcal{T}(\mathcal{N}) = Q \mathcal{T}(\mathcal{M})\).

The main theorem can now be stated.
12.8 Theorem. Let \( \mathcal{N} \) and \( \mathcal{M} \) be nests on a separable Hilbert space. The following are equivalent:

1) \( Q \mathcal{T}(\mathcal{N}) = Q \mathcal{T}(\mathcal{M}) \).

2) \( \mathcal{N} \) and \( \mathcal{M} \) are compactly perturbed nests.

3) \( \mathcal{N} \) and \( \mathcal{M} \) have finite perturbations which are approximately unitarily equivalent by compact perturbations of the identity.

4) \( \mathcal{N} \) and \( \mathcal{M} \) have finite perturbations which are similar by a compact perturbation of the identity.

The proof of 1) implies 2) follows from Lemmas 12.9-12.14 and Theorem 12.15. Theorem 12.16 shows 2) implies 3). And 3) implies 4) is a consequence of Lemma 12.17 and Theorem 12.18. The implication 4) implies 1) has already been done.

12.9 Lemma. Let \( \mathcal{N} \) and \( \mathcal{M} \) be nests with \( Q \mathcal{T}(\mathcal{N}) = Q \mathcal{T}(\mathcal{M}) \). Let \( \Phi \) be an expectation of \( \mathcal{B}(\mathcal{H}) \) onto \( \mathcal{M}' \). Then the map \( N \rightarrow P(N) - \Phi(P(N)) \) is norm continuous and compact valued.

Proof. First, we show that \( \delta = \delta_{P(N)} \) is a derivation of \( \mathcal{M}' \) into \( K \). For \( \mathcal{M}' \) belongs to \( Q \mathcal{T}(\mathcal{N}) \cap Q \mathcal{T}(\mathcal{M})' \), and thus any \( M \) in \( \mathcal{M}' \) can be written as \( M = A+K = B^*+L \) where \( A \) and \( B \) belong to \( \mathcal{T}(\mathcal{N}) \) and \( K \) and \( L \) are compact. Thus

\[
\delta(M) = P(N)(B^*+L)P(N)^\perp - P(N)^\perp(A+K)P(N) \\
= P(N)L P(N)^\perp - P(N)^\perp K P(N)
\]  

(12.9.1)

This is compact valued. Hence by the Johnson-Parrott Theorem 10.12, \( \delta = \delta_K \) where \( K = P(N) - \Phi(P(N)) \) is compact, and \( ||K|| \leq ||\delta_{P(N)}|| \).

Let \( N_k \) be a sequence in \( \mathcal{N} \) converging to \( N \). Then \( P_k = P(N_k) \) converges to \( P = P(N) \) in the strong operator topology by Proposition 2.13. Let \( \delta_k = \delta_{P_k} \). By (12.9.1),

\[
(\delta - \delta_k)(M) = (PLP^\perp - P^\perp K P) - (P_k L P_k^\perp - P_k^\perp K P_k) \\
= (P-P_k)LP^\perp - P_k L (P-P_k) \\
+ (P-P_k)KP - P_k K (P-P_k)
\]

By Proposition 1.18, \( (\delta - \delta_k)(M) \) converges to 0 in norm as \( k \) tends to \( \infty \). Now consider \( \delta \sum \bigoplus_{P-P_k} \delta = \sum \bigoplus \delta - \delta_k \) which is derivation of \( (\mathcal{M}')^{[\infty]} \) into the compacts because of the previous computation. By the Johnson-Parrott Theorem 10.12, there is a compact operator \( K' = \sum \bigoplus K'_k \) such that \( \delta - \delta_k = \delta_{K'_k} \). Now \( K_k = P(N_k) - \Phi(P(N_k)) \) satisfies \( \delta - \delta_k = \delta_{K-K_k} \) and \( ||K-K_k|| \leq ||\delta - \delta_k|| \leq 2||K'_k|| \). This tends to zero as \( k \) tends to infinity. Thus the map taking \( N \) to \( P(N) - \Phi(P(N)) \) is norm continuous. ■
12.10 Lemma. Let $P$ be a projection such that $P^\perp TP$ is compact for every $T$ in $\mathcal{T}(\mathcal{M})$. Then there is an $M$ on $\mathcal{M}$ such that $P-P(M)$ is compact.

Proof. In particular, $P$ is in the essential commutant of $\mathcal{M}'$, since $PM-PM = (P^\perp M^*P)^* - P^\perp MP$ is compact for every $M$ in $\mathcal{M}'$. So by the Johnson-Parrott Theorem 10.12, $P = A+K$ where $K$ is compact and $A$ belongs to $\mathcal{M}''$. Now, $P = P^* = ReA + ReK$, so we may suppose that $A = A^*$. Also, $A-A^2$ is compact, and thus $\sigma_e(A)$ is contained in $[0,1)$. So using the functional calculus of $A$, one obtains a projection $Q$ in $\mathcal{M}''$ such that $P-Q$ is compact. Define

$$M_0 = \sup \{ M \in \mathcal{M} : P(M)Q^\perp \text{ is compact} \}$$

and

$$M_1 = \inf \{ M \in \mathcal{M} : P(M)_-^\perp Q \text{ is compact} \}.$$ 

For each $M$ in $\mathcal{M}$, either $P(M)Q^\perp$ or $P(M_1)^\perp$ is compact; for otherwise, there is an infinite rank partial isometry

$$U = P(M)Q^\perp UQP(M_1)^\perp.$$ 

This belongs to $\mathcal{T}(\mathcal{M})$ by Lemma 2.8. But $Q^\perp UQ = U$ is not compact, contradicting the essential invariance of $Q$ (and $P$). It follows that $M_1 \leq M_0$.

If there is an $M$ in $\mathcal{M}$ with $M_1 < M < M_0$, then $P(M)Q^\perp$ and $P(M_1)^\perp Q$ are both compact. Hence

$$P(M)-Q = P(M)Q^\perp - P(M)^\perp Q$$

is compact. Likewise, if $M_1 = (M_0)_- < M_0$, then $P(M_1)Q^\perp$ and $P(M_1)^\perp Q = P(M_0)_-^\perp Q$ are both compact. So as above, $P(M_1)-Q$ is compact.

In the remaining case, $M_0 = M_1$ and one of $P(M_0)Q^\perp$ or $P(M_0)^\perp Q$ is compact. It must be shown that both are compact, implying that $Q-P(M_0)$ is compact. Suppose that $P(M_0)Q^\perp$ is compact but $P(M_0)^\perp Q$ is not. For every $M > M_0$, $P(M)^\perp Q$ is a compact projection. Thus it is finite rank and is therefore the sum of minimal projections in $\mathcal{M}''$. These minimal projections are precisely the atoms of $\mathcal{M}$. Let $M_n$ be a decreasing net with limit $M_0$. Then $P(M_n)^\perp Q$ converges strongly to $P(M_0)^\perp Q$, and thus $P(M_n)^\perp Q = \sum A_n$ where $A_n$ are finite rank atoms of $\mathcal{M}$. Also, if $M > M_0$, then $(P(M)-P(M_0))Q^\perp$ is not compact. This projection is the strong limit of $(P(M)-P(M_n))Q^\perp$ and thus this net is eventually non-zero. Hence one may construct a decreasing sequence $M_j$, $j \geq 2$ so that $P(M_j)A_j = 0$ and $R_j = (P(M_j)-P(M_{j+1}))Q^\perp \neq 0$. Define a partial isometry
\[ U_j = P(M_j)R_j U_j A_j P(M_j) \perp \]
for \( j \geq 2 \). This belongs to \( T(M) \) by Lemma 2.8, and so the infinite rank partial isometry \( U = \sum_{j \geq 2} U_j \) belongs to \( T(M) \). But \( U = Q^\perp U Q \) contradicts the essential invariance of \( Q \). So \( P(M_0) Q \) must have been compact as claimed.

One can repeat the proof in the case \( P(M_0) Q \) is compact but \( P(M_0) Q^\perp \) is not by reversing the order considerations. A contradiction is obtained as above. In all these cases, one has found an \( M \) in \( M \) so that \( P(M) = Q \) and thus \( P(M) = P \) is compact.

**12.11 Corollary.** Let \( \Theta \) be a map of intervals \( E = P(N_1) - P(N_2) \) onto \( M'' \) defined by \( \Theta(E) = \chi(\Phi(E)) \) when \( \chi \) is the characteristic function of \([\frac{1}{2},1]\). Then \( \Theta(E) \) belongs to \( C^*(M) \). \( \Theta(E) - E \) is compact for every \( E \), and when \( E_\alpha \) converges strongly to zero, \( \Theta(E_\alpha) - E_\alpha \) converges to zero in norm.

**Proof.** By Lemmas 12.9 and 12.10, \( \Phi(P(N_1)) \) differs from some \( P(M_i) \) by a compact operator. Thus \( \Phi(E) \) differs from an interval of \( M \) by a compact operator in \( M'' \). Every compact operator in \( M'' \) is normal, and thus a norm convergent sum \( \sum_{n \in A} \lambda_n A_n \) where \( A_n \) are minimal, finite rank projections in \( M'' \), and thus are atoms of \( M \). Thus \( M'' \cap K \) is contained in \( \sigma(\Phi(E)) \). Furthermore, \( \chi \) is a continuous function of \( \sigma(\Phi(E)) \) which is a countable subset of \([0,1]\) with \([0,1]\) as its only possible limit points. So \( \Theta(E) \) belongs to \( C^*(M) \) and \( \Phi(E) - \Theta(E) \) is compact. By Lemma 12.9, the map taking \( E \) to \( E - \Phi(E) \) is continuous on the strong operator topology on \( E \) (induced from the order topology on \( N \)) to the norm topology on \( K \). The map of \( E \) to \( \Phi(E) - \chi(\Phi(E)) \) is continuous at \( E \) provided that \( \sigma(\Phi(E)) \) does not contain \( \frac{1}{2} \). In particular, this is the case if \( \| E - \Phi(E) \| < \frac{1}{2} \). This holds eventually for \( E_\alpha \) if \( E_\alpha \) converges strongly to zero. So \( \Theta(E) - E \) is continuous at zero.

Lemma 12.10 shows that \( N \) and \( M \) are equal modulo the compact operators. It must now be shown that the atoms of \( N \) and \( M \) essentially match up, and fit into the nests in the "same places". To locate the atoms, we introduce the maximal ideal space \( M_M \) of \( C^*(N) = C^*(P(N) : N \in N) = C^*(N) + K/K \). This is an invariant of \( \# T(M) \) since Lemma 12.10 shows that \( \# N \) is determined as the essentially invariant projections of \( Q T(N) \). The set \( M_M \) sits naturally as a closed subset of \( M_M \), for if \( \phi \) belongs to \( M_M \), then \( \phi \circ \pi \) belongs to \( M_M \). (Recall sections 6.1-6.2 about \( M_M \).)
12.12 Proposition. The complement $M_H \setminus M'_H$ consists of the evaluations $\delta_A$ at finite rank atoms of $H$.

Proof. Every compact operator in $C^*(H)$ is normal, and thus is a sum $\sum_{n \geq 1} \lambda_n A_n$ where $A_n$ are minimal, finite rank projections (i.e. atoms) in $C^*(H)$. The maximal ideals in $M'_H$ correspond in a bijective way with the maximal ideals of $C^*(H)$ which contain all of $K \cap C^*(H)$. Clearly $ker \delta_A$ does not contain $A$, so evaluation at finite rank atoms are not in $M'_H$. On the other hand, if $\phi$ in $M_H$ is not evaluation at a finite rank atom, then $\phi(A) = 0$ for every finite atom $A$ and hence $ker \phi$ contains all $K \cap C^*(H)$. So, $\phi$ belongs to $M'_H$.

Put a partial order $\ll$ on the intervals of $H$ by setting $E \ll F$ if and only if $E \subseteq T(H)F = E B (H)F$. In particular, if $\mathcal{I} = \{0 = F_0 < F_1 < \ldots < F_n = H\}$ is a finite subnest of $H$, then $E_j = P(F_j) - P(F_{j-1})$ for $1 \leq j \leq n$ is a partition of $H$ into intervals such that $E_1 \ll E_2 \ll \ldots \ll E_n$.

The space $M_H$ is linearly ordered (Chapter 6), and $M_H \setminus M'_H$ consists of the disjoint union of countably many maximal open intervals of finite rank atoms. The end points of these intervals belong to $M'_H$, and serve to mark the place of a finite rank atom in $M'_H$. So define the *markers* $M(\delta_A)$ to be the end points of the maximal interval of finite rank atoms containing $\delta_A$. It may occur that one open interval in $M_H \setminus M'_H$ is an initial or terminal segment. So in this case one end point may be missing. The typical example is a nest $\mathcal{P} = \{P_n, n \geq 1\}$ of finite projections. In this case $M_\mathcal{P} = \{\delta_n, n \geq 1, \phi_0\}$ where $\delta_n$ is evaluation at the atom $P_n - P_{n-1}$ and $\phi_0(P) = 0$ if $P \neq I$. $M'_\mathcal{P} = \{\phi_0\}$, so the left end point of $M_H \setminus M'_\mathcal{P}$ is not defined in $M'_\mathcal{P}$.

Suppose that $A$ and $B$ are atoms of $H$ with $M(A) < M(B)$. That is, $M(A) = \{\phi_0, \phi_1\}$ and $M(B) = \{\psi_0, \psi_1\}$, and $\phi_0 < \psi_0$ or equivalently $\phi_1 \leq \psi_0$ since $\phi_1$ is the immediate successor of $\phi_0$ in $M'_H$. Let $N$ be the least element of $\mathcal{N}$ containing $A$, and let $M$ be the greatest element of $\mathcal{N}$ orthogonal to $B$. It follows that $\phi_1(N) = 0$ and $\phi_1(M) = 1$. So $E = P(M) - P(N)$ is a test interval in $\mathcal{E}_b$ (i.e. $\phi_1(E) = 1$) with $A \ll E \ll B$. Since $\phi_1$ annihilates the compact operators, $E$ has infinite rank.
12.13 Lemma. Suppose that \( Q \subseteq T(M) = Q \subseteq T(N) \), and let \( A \) and \( B \) be the sets of atoms of \( N \) and \( M \) respectively. There are finite subsets \( A_0 \) and \( B_0 \) of \( A \) and \( B \) such that for every \( A, A' \) in \( A \setminus A_0 \):

i) \( \Theta(A) \) is an atom in \( B \setminus B_0 \).

ii) \( \|\Theta(A) - A\| < \frac{1}{n} \) and rank \( \Theta(A) = \text{rank } A \).

iii) \( M(\Theta(A)) = M(A) \).

iv) \( A \ll A' \) implies \( \Theta(A) \ll \Theta(A') \).

Furthermore, \( \Theta \) is a bijection between \( A \setminus A_0 \) and \( B \setminus B_0 \).

Proof. Let \( A = \{A_n, n \geq 1\} \). By Corollary 12.11, \( \|A_n - \Theta(A_n)\| < \frac{1}{n} \) for all except finitely many atoms. After deleting these, rank \( A_n = \text{rank } \Theta(A_n) \). Also, \( \Theta(A_m) = \Theta(A_n) \) implies \( \|A_n - A_m\| < 1 \), and so \( A_n = A_m \) and \( \Theta \) is one to one. If \( \Theta(A_n) \) is not an atom, then there is a partial isometry \( U_n = \Theta(A_n)U_n\Theta(A_n) \) such that \( \text{dist}(U_n, T(M)) = 1 \). Suppose this occurs for infinitely many atoms \( A_n \). Chose an infinite subsequence \( \Lambda \) so that

\[
\sum_{n \in \Lambda} \|A_n - \Theta(A_n)\| < \infty .
\]

The operator \( U = \sum_{n \in \Lambda} U_n \) is not in \( Q \subseteq T(M) \). However,

\[
U - \sum_{n \in \Lambda} A_n U_n A_n = \sum_{n \in \Lambda} (\Theta(A_n) - A_n)U_n + A_n U_n (\Theta(A_n) - A_n) .
\]

The right hand side is a norm convergent sum of compact operators, and thus \( U \) is a compact perturbation of \( \sum_{n \in \Lambda} A_n U_n A_n \) which belongs to \( T(M) \).

This contradicts the equality \( Q \subseteq T(N) = Q \subseteq T(M) \). So i) and ii) hold.

Suppose that \( (A_n, A'_n) \) are disjoint pairs in \( A \) with \( A_n \ll A'_n \) and \( \Theta(A_n) \gg \Theta(A'_n) \). Then there is a partial isometry of the form \( U_n = \Theta(A_n)U_n\Theta(A'_n) \), and it follows that \( \|U_n\| = \text{dist}(U_n, T(M)) = 1 \). As above, one obtains a contradiction if the set of pairs is infinite. Thus after deleting finitely many more atoms, iv) holds.

Similarly, suppose that \( M(\Theta(A_n)) \neq M(A_n) \) infinitely often. For definiteness, suppose \( M(A_n) \ll M(\Theta(A_n)) \) infinitely often. This means that there is a \( \phi_n \) in \( M'_f = M'_f \) and intervals \( E_n \) of \( N \) and \( F_n \) of \( M \) such that \( \phi_n(E_n) = \phi(F_n) = 1 \), and \( A_n \ll E_n \) and \( F_n \ll B_n \). Since \( \phi_n \) annihilates the compact operators, \( \phi_n(\Theta(E_n)) = 1 \) and hence \( P_n = \Theta(E_n)F_n \) is an infinite rank projection. Repeating once more the argument of the first paragraph, drop to a subsequence \( \Lambda \) so that \( \sum_{n \in \Lambda} \|A_n - \Theta(A_n)\| < \infty \) and construct rank one partial isometries \( U_n = B_nU_nP_n \). Then \( U = \sum_{n \in \Lambda} U_n \) is not in \( Q \subseteq T(M) \), but does belong to \( Q \subseteq T(N) \). So iii) holds.
Let $A_0$ be the finite collection of atoms deleted from $A$ in order to satisfy i)-iv). Let $B_0 = B \setminus \Theta(A \setminus A_0)$. It must be shown that $B_0$ is finite. By reversing the role of $\mathcal{M}$ and $\mathcal{N}$, one obtains a one to one map $\Theta^*$ of $B$ into $C^*(\mathcal{N})$ such that $\Theta^*(B)$ is an atom except finitely often and $\lim_{n \to \infty} \|\Theta^*(B_n) - B_n\| = 0$. So for $n$ sufficiently large,$$
abla \leq \Theta^*(B_n) \leq 1$$and hence $\Theta(\Theta^*(B_n)) = B_n$. Hence $\Theta$ maps onto all but finitely many atoms of $B$. So $B_0$ is finite. ■

12.14 Lemma. Let $E_j$ and $F_j$, $1 \leq j \leq n$, be two families of pairwise orthogonal projections such that $E_j - F_j$ is compact and $\|E_j - F_j\| < 1$, $1 \leq j \leq n$. Then $\text{codim} \sum_{j=1}^{n} E_j = \text{codim} \sum_{j=1}^{n} F_j$.

Proof. Since $\|E_j(E_j - F_j)E_j\| < 1$, $E_j F_j E_j \leq \epsilon E_j$ for some $\epsilon > 0$, $1 \leq j \leq n$. Similarly, $F_j E_j F_j \geq \epsilon F_j$. Let $T = \sum_{j=1}^{n} E_j F_j$. Notice that $$\sum_{j=1}^{n} F_j \geq TT = \sum_{j=1}^{n} F_j E_j F_j \geq \epsilon \sum_{j=1}^{n} F_j$$and $$\sum_{j=1}^{n} E_j \geq TT^* = \sum_{j=1}^{n} E_j F_j E_j \geq \epsilon \sum_{j=1}^{n} E_j .$$So $T$ is bounded below on its domain $(\sum_{j=1}^{n} F_j)\mathcal{N}$ which is mapped onto its range $(\sum_{j=1}^{n} E_j)\mathcal{N}$. Now $T$ is a compact perturbation of $\sum_{j=1}^{n} F_j$ which is self-adjoint, and thus $T$ is Fredholm of index zero, or is not semi Fredholm. So if $\sum_{j=1}^{n} F_j$ has finite codimension, then $0 = \text{ind} T = \text{codim} \sum_{j=1}^{n} F_j - \text{codim} \sum_{j=1}^{n} E_j$. Likewise for $\sum_{j=1}^{n} E_j$. In the remaining case, both have infinite codimension. ■

12.15 Theorem. If $Q T(\mathcal{N}) = Q T(\mathcal{M})$, then $\mathcal{N}$ and $\mathcal{M}$ are compactly perturbed nests.

Proof. Let $\Theta$ be the map given by Corollary 12.11. The first paragraph of this proof modifies $\mathcal{N}$ and $\mathcal{M}$ so that $\|\Theta(A) - A\| < 1$ for every infinite rank atom of $\mathcal{N}$. Consider any infinite rank atom $A$ in $A_0$, the finite set of
atoms provided by Lemma 12.13. Now $\tilde{A}$ is a minimal projection in $C^*(\tilde{N})$. This $C^*$-algebra equals $C^*(\tilde{M})$ by Lemma 12.10, so $\tilde{A}$ is a minimal projection in $C^*(\tilde{M})$. Thus there is an infinite atom $B$ of $\mathcal{M}$ so that $A - B$ is compact. Choose projections $A'$ and $B'$ of finite codimension in $A$ and $B$ respectively so that $\|A' - B'\| < \frac{1}{4}$. Let $R$ be the sum of the finite atoms in $A_0$ and of $(A - A')$ for the infinite atoms. Likewise, define $S$ to be the corresponding sum for $B_0$. Extend the definition of $\Theta$ to intervals of $\mathcal{M}^S$ onto $\mathcal{M}^S$ by setting $\Theta(A') = B'$ and $\Theta(R) = S$.

For each $\phi$ in $\mathcal{M}_h^S$ (except $\delta_R$), there is a test interval $E_\phi$ such that for every interval $E \leq E_\phi$, one has $\|E - \Theta(E)\| < \frac{1}{4}$. This follows since it is true for atoms by Lemma 12.13 ii), and holds at other points by the continuity at zero guaranteed by Corollary 12.11. Thus there is a partition of $\mathcal{M}^R$ into intervals $R = E_0 \ll E_1 \ll ... \ll E_n$ so that $\|\Theta(E) - E\| < \frac{1}{4}$ for all intervals $E \leq E_j$, $1 \leq j \leq n$. Let $F_j = \Theta(E_j)$, $0 \leq j \leq n$. For $1 \leq i < j \leq n$,

$$\|F_i F_j\| < \|F_i - E_i\|E_j\| + \|E_j(F_j - F_i)\| < 1 .$$

Since $F_i$ and $F_j$ commute, $F_i F_j = 0$ for $1 \leq i < j \leq n$. By Lemma 12.14, rank $R = \text{rank } S$.

Define a map $\theta$ of $\mathcal{M}^R$ into $\mathcal{M}^S$ as follows. If $\sum_{j<k} E_j < N \leq \sum_{j \leq k} E_j$, set

$$\theta(N) = \sum_{j \leq k} F_j + \Theta(P(N)E_k) .$$

Now $E = P(N)E_k$ is an interval and thus $\Theta(E) = F \leq F_k$ differs from an interval by a finite linear combination of finite atoms. However by Lemma 12.13 (iii) and (iv), $F$ must be an interval. In fact, $F$ must be an initial segment of $F_k$ for the same reasons. So $\theta(N)$ belongs to $\mathcal{M}^S$. By Lemma 12.13 (ii), and the previous paragraph, $\theta$ preserves the dimension of atoms. Thus, $\theta$ is a dimension preserving order isomorphism of $\mathcal{M}^R$ into $\mathcal{M}^S$ such that $\theta(\mathcal{M}^R)$ and $\mathcal{M}^S$ have the same atoms. Both are complete nests, and hence $\theta$ is surjective.

With $N, E$ and $F$ as above, $P(N) - P(\theta(N)) = \sum_{j \leq k} E_j - F_j + E - F$ is compact for all $N$ in $\mathcal{M}$. Suppose that $\sum_{j \leq k} E_j \leq P(N_\alpha) \leq \sum_{j \leq k} E_j$, and $N_\alpha$ converges to $N$. Set $E_\alpha = P(N_\alpha)E_k$. Then

$$(P(N) - P(\theta(N)) - (P(N_\alpha) - P(\theta(N_\alpha))) = (E - \Theta(E)) - (E_\alpha - \Theta(E_\alpha)) .$$

Since $E_\alpha$ converges strongly to $E$, this term converges to zero in norm by Corollary 12.11. Hence it follows easily that the map of $N$ to $P(N) - P(\theta(N))$ is norm continuous on $\mathcal{M}$ (with the order topology). So $\mathcal{M}$ and $\mathcal{N}$ are compactly perturbed nests.
12.16 Theorem. Let $\mathcal{N}$ and $\mathcal{M}$ be nests, and let $\theta$ be a dimension preserving order isomorphism of $\mathcal{N}$ and $\mathcal{M}$ such that $\theta-id$ belongs to $C_n(\mathcal{M},K)$. Then one can find finite rank projections $E$ in $\mathcal{N}'$ and $F$ in $\mathcal{M}'$ dominated by the infinite dimensional atoms such that $\mathcal{N}^E$ and $\mathcal{M}^F$ are approximately unitarily equivalent by a sequence $U_n$ of unitaries such that $U_n-I$ is compact.

Proof. Extend $\theta$ to a map $\Theta$ of intervals $E = P(N_1)-P(N_2)$ by $\Theta(E) = P(\theta(N_1))-P(\theta(N_2))$. We first show how to modify $\mathcal{N}$ so that $\|\Theta(A) - A\| < 1$ for all infinite rank atoms. The continuity of $\theta-id$ implies that $\Theta-id$ is continuous from the strong operator topology on the intervals to the norm topology on $K$. Since $\mathcal{N}$ is compact, this continuity implies there is a partition $E_1 < E_2 < ... < E_n$ of $\mathcal{N}$ so that $E_j$ is either an atom or $\|\Theta(E) - E\| < 1$ for every interval $E \leq E_j$. Let $F_j = \Theta(E_j)$. Consider the infinite rank atoms $E_j$ such that $\|E_j-F_j\| = 1$ and choose finite rank projections $A_j < E_j$ and $B_j < F_j$ such that $\|(E_j-A_j)-(F_j-B_j)\| < 1$. Let $E_j' = E_j-A_j$, $F_j' = F_j-B_j$, and let $E_0$ be the sum of the $A_j$ and let $F_0$ be the sum of the $B_j$. One can use Lemma 12.14 to show that $rank E_0 = rank F_0$ provided one notes that if $E_j$ is a finite rank atom and $\|E_j-F_j\| = 1$, then $rank E_j = rank F_j$ because $\theta$ preserves dimension. So, replace $\mathcal{N}$ by $\mathcal{N}^{\theta_0}$ and $\mathcal{M}$ by $\mathcal{M}^{\theta_0}$ and modify $\theta$ to $\theta'$ in the obvious way. It is easy to verify that $\theta'$ is now a dimension preserving order isomorphism of $\mathcal{N}^{\theta_0}$ onto $\mathcal{M}^{\theta_0}$ such that $\theta'-id'$ belongs to $C_n(\mathcal{M}^{\theta_0},K)$. Moreover, the extended map $\Theta'$ has the property that $\|\Theta'(A) - A\| < 1$ for every infinite rank atom. For convenience of notation, we will assume that our original nests have this property, so that the "orws" can be dropped.

Let $0 < \epsilon < 1$ be given. Since $\mathcal{N}$ is compact and $\Theta-id$ is continuous onto $K$, one can obtain as before a partition $E_1 < E_2 < ... < E_n$ of $\mathcal{N}$ such that either $\|E-\Theta(E)\| < \epsilon$ for every interval $E \leq E_j$ or $E_j$ is an atom. Let $F_j = \Theta(E_j)$. If $\|E_j-F_j\| < 1$, let $U_j$ be the partial isometry in the polar decomposition of $F_jE_j$. Since $F_j-E_j$ is compact and $\|E_jF_j\| < 1$, $U_j$ takes $E_j\mathcal{N}$ onto $F_j\mathcal{N}$ and $U_j-E_j$ is compact. If $\|E_j-F_j\| = 1$, then $E_j$ is a finite rank atom and $rank E_j = rank F_j$. So one can define a partial isometry $U_j$ of $E_j\mathcal{N}$ onto $F_j\mathcal{N}$. Let $U = \sum_{j=1}^n U_j$.

This is a unitary operator, and $U-I = \sum_{j=1}^n U_j-E_j$ is compact. Moreover, $UE_jU^* = F_j$ for $1 \leq j \leq n$.

Let $N$ belong to $\mathcal{N}$, and choose $k$ so that $\sum_{j<k} E_j < P(N) \leq \sum_{j\leq k} E_j$.

Let $E = P(N)E_k$ and $F = \Theta(E)$. Then $P(\theta(N)) = \sum_{j<k} F_j+F$ and $F_j-F_j'$ is compact.
\[ U^P(N)U^* = \sum_{j<k} F_j + U_k E_k^* . \]

So

\[ \| P(\theta(N)) - U^P(N)U^* \| = \| F - U_k E_k^* \| = \| F_{U_k} - U_k E \| . \]

If \( E_k \) is an atom, then \( E = E_k \) and so this term is zero. Otherwise \( \| E_k - F_k \| < \varepsilon \) and hence \( E_k F_k E_k \geq (1-\varepsilon)E_k \). Let \( R = (E_k^\perp + E_k F_k E_k)^{\perp \perp} \). Then \( U_k = F_k E_k R \) and \( \| R \| \leq (1-\varepsilon)^{-\delta} \). So

\[ \| F_{U_k} - U_k E \| \leq \| F_{E_k} E_k - F_k E_k E \| \| R \| \]
\[ = \| F_{E_k} E_k^{\perp \perp} - F_k^{\perp \perp} F_k E \| \| R \| \]
\[ \leq (1-\varepsilon)^{-\delta} \max(\{\| F(F-E)E_k E_k^{\perp \perp} \|, \| F_k^{\perp \perp} F_k F - E \| \}) \]
\[ < \varepsilon(1-\varepsilon)^{-\delta} . \]

Hence \( \| \theta - AdU \| < \varepsilon(1-\varepsilon)^{-\delta} \).

It remains to choose a sequence \( U_n \) with \( \varepsilon_n \) tending to 0.

\[ \boxed{\text{12.17 Lemma. Let } \mathcal{H} \text{ and } \mathcal{M} \text{ be approximately unitarily equivalent via unitaries } U_n, \text{ and let } \theta \text{ be the induced order isomorphism. Let } \delta = \| \theta - Id \|. \text{ Given } \varepsilon > 0, \text{ there is an invertible operator } T \text{ such that } \| T - I \| \leq 10\delta \text{, and the map } \theta_T(N) = TN \text{ satisfies } \| \theta_T - \theta \| < \varepsilon. \text{ If } U_n - I \text{ is compact for all } n \geq 1, \text{ then } T - I \text{ is compact also.} \}

\text{Proof. As in the previous lemma, extend } \theta \text{ to a map } \Theta \text{ of intervals. Then } \| \Theta - id \| \leq 2\| \theta - id \| \leq 2\delta. \text{ Let } U = U_n \text{ for } n \text{ so large that } \| \theta_{U_n} - \theta \| < \varepsilon \leq \delta. \text{ If } \delta \geq 1/5, \text{ take } T = U. \text{ Otherwise, we can assume that } \delta < 1/5. \text{ Compute } dist(U, T(M)):\]

\[ \| P(N)^\perp UP(N) \| = \| P(N)^\perp P(U(N)U(N)) \|
\[ \leq \| P(U(N)) - P(\theta(N)) \| + \| P(\theta(N)) - P(N) \|
\[ \leq \| \theta_U - \theta \| + \| \theta - id \| < \varepsilon + \delta \leq 2\delta . \]

By Arveson's distance formula, \( dist(U, T(M)) < 2\delta \). So, choose \( A \) in \( T(M) \) such that \( \| U - A \| < 2\delta. \text{ If } U = I + K \text{ and } K \text{ is compact, then by Theorem 12.1,} \]

\[ dist(U, T(M)) = dist(K, T(M)) = dist(K, T(M) \cap K) . \]

So one may take \( A - I \) to be compact in this case.

Since \( \| U - A \| < 2/5, \text{ } A \text{ is invertible in } B(M), \text{ and } \| A^{-1} \| \leq 5/3. \text{ It must be shown that } A^{-1} \text{ belongs to } T(N), \text{ or equivalently, that } AN = N \text{ for every } N \text{ in } N. \text{ If it were otherwise, then since } AN \text{ is a proper subspace of } N, \text{ there would be a unit vector } x \text{ in } N \text{ orthogonal to } AN. \text{ Now} \]

\[ \Theta = \begin{cases} A^{-1} & \text{if } \theta_N = \theta_M \text{ and } A \text{ is invertible in } B(N) \\ \text{otherwise} & \end{cases} \]
Quasitriangular Algebras

\[ \|P(N) - P(Un)\| < \|id - \theta\| + \|\theta - \theta U\| \leq 2/5, \]

and \( y = P(Un)z = Uz \) for some vector \( z \) in \( N \) with \( \|z\| \leq 1 \). So
\[ \|x - Ax\| \leq \|x - y\| + \|(U - A)x\| \leq 4/5 < 1. \]

This contradicts the assumption that \( AN \neq N \). So \( A^{-1} \) belongs to \( \mathcal{T}(N) \).

Let \( T = U A^{-1} \). Then
\[ \|T - I\| = \|(U - A)A^{-1}\| < 2\delta(5/3) < 4\delta. \]

And if \( N \) belongs to \( \mathcal{N} \), \( TN = U(A^{-1}N) = UN \) so \( \theta_T = \theta_U \). Hence
\[ \|\theta_T - \theta\| < \epsilon. \]  

**12.18 Theorem.** Let \( \mathcal{N} \) and \( \mathcal{M} \) be approximately unitarily equivalent via unitaries \( U_n \), and let \( \theta \) be the induced order isomorphism. Then \( \mathcal{N} \) and \( \mathcal{M} \) are similar via an invertible operator \( S \) such that \( \theta_S = \theta \). Given \( \epsilon > 0 \), \( S \) may be taken to be \( U + L \) where \( U \) is unitary and \( \|L\| < \epsilon \). If furthermore, \( U_n - I \) is compact for all \( n \geq 1 \), \( S - I \) may be taken to be compact, and also of the form \( U + K \) where \( U \) is unitary in \( I + K \), \( K \) is compact, and \( \|K\| < \epsilon \).

**Proof.** Let \( \epsilon > 0 \) be given, and choose a decreasing sequence \( \epsilon_n, n \geq 1 \) such that \( \prod_{n \geq 1} (1 + 10\epsilon_n) < 1 + \epsilon \). Choose a unitary \( U = U_{n_0} \) so that \( \|\theta_U - \theta\| < \epsilon_1 \). Recursively apply Lemma 12.17 to obtain operators \( T_n \)
with \( \|T_n - I\| < 10\epsilon_n \) so that \( \|\theta_{T_n T_{n-1} \ldots T_2 U - \theta}\| < \epsilon_{n+1} \). If each \( U_n - I \) is compact, then make \( T_n - I \) compact also. The infinite product \( T = \lim_{n \to \infty} T_n T_{n-1} \ldots T_2 U \) converges in norm, and
\[ \|T - U\| \leq \prod_{n \geq 1} \|T_n - I\|^{-1} = \epsilon \]
(see Exercise 12.4). If furthermore, each \( T_n - I \) is compact, then \( T - U \) is compact.

For any operator \( X \), \( \|P(XN) - P(N)\| \leq 2\|X - I\| \); for if \( y \) is any unit vector in \( N \),
\[ \|y - \frac{Xy}{\|Xy\|}\| \leq \|y - Xy\| + \|X\|^{-1} \leq 2\|X - I\| \]
and conversely, every unit vector in \( XN \) has the form \( Xy/\|Xy\| \) for some unit vector \( y \) in \( N \). Thus
\[ \|\theta_T - \theta\| \leq \|\theta_{T - \theta \ldots T_2 U} + \theta_{T \ldots T_2 U - \theta}\| \leq 2\|T - T_{\ldots T_2 U}\| + \epsilon_{n+1}. \]

This tends to zero as \( N \) increases, so \( \theta_T = \theta \) as desired. ■
12.19 Example. It is possible that \( Q \mathcal{T}(\mathcal{H}) = Q \mathcal{T}(\mathcal{M}) \), and that \( \mathcal{N} \) is unitarily equivalent to \( \mathcal{M} \), but no unitary of the form \( I + K \) with \( K \) compact will work. In our example, it will also be seen that the isomorphism \( \theta \) of \( \mathcal{H} \) onto \( \mathcal{M} \) may be arbitrarily small, and the unitary implementing it is always far from the identity.

Let \( \{ e_n, n \geq 1 \} \) be an orthonormal basis for \( \mathcal{H} \), and let \( P_n \) be the span \( \{ e_k, 1 \leq k \leq n \} \). Let \( P = \{ \{ 0 \}, P_n, n \geq 1, \mathcal{H} \} \). Any other nest \( Q = \{ \{ 0 \}, Q_n, n \geq 1, \mathcal{H} \} \) with \( \text{dim} Q_n = n \) for all \( n \) is unitarily equivalent to \( P \). It follows from Theorem 12.2, \( Q \mathcal{T}(Q) = Q \mathcal{T}(P) \) provided \( \lim_{n \to \infty} \| P_n - Q_n \| = 0 \). The converse follows from Theorem 12.8 or directly by more elementary means (see Exercise 12.2).

Recall Example 4.1. Let \( t_{ij} = 0 \) if \( i \geq j \), and \( t_{ij} = \frac{1}{j-1} \) if \( j > i \).

Let \( T_n \) be the matrix

\[
T_n = [t_{ij}] = \begin{bmatrix}
0 & 1 & \frac{1}{2} & \frac{1}{3} & \frac{1}{n-1} \\
0 & 1 & \frac{1}{2} & \frac{1}{n-2} & 0 \\
0 & 0 & 1 & \frac{1}{n-3} & 0 \\
0 & 0 & 0 & 0 & 0
\end{bmatrix}
\]

Then \( \| T_n \| > 4/\log n \) but \( \| T_n - T_n^* \| \leq \pi \). Let

\[
R_n = \frac{T_n + T_n^*}{\| T_n + T_n^* \|} \quad \text{and} \quad S_n = \frac{T_n}{\| T_n + T_n^* \|}.
\]

Since \( \| T_n \| - \pi \leq \| T_n + T_n^* \| \leq \| T_n \| + \pi \), one has \( \lim_{n \to \infty} \| S_n \| = 1 \), and \( \lim_{n \to \infty} \| R_n - S_n \| = 0 \). Let \( N_n \) be the span of the first \( k \) basis vectors, and let \( \tau_n \) be the \( n \times n \) matrices which are upper triangular with respect to \( \{ N_n, 1 \leq k \leq n \} \). Since \( S_n \) belongs to \( \tau_n \), \( \lim_{n \to \infty} \text{dist}(R_n, \tau_n) = 0 \). Let \( U_n = e^{iR_n} \) and let \( V_n = e^{iS_n} \). Then \( U_n \) is unitary, \( V_n \) belongs to \( \tau_n \), and the diagonal \( \Delta(V_n) = I \).
\[ \|U_n - V_n\| = \left\| \sum_{k \geq 0} \frac{(iR_n)^k - (iS_n)^k}{k!} \right\| \leq \sum_{k \geq 1} \frac{1}{k!}\|R_n^k - S_n^k\| \]
\[ \leq \sum_{k \geq 1} \frac{1}{k!} \left( \sum_{j=0}^{k-1} \|S_n\| |\hat{\lambda}_j| \right) \|R_n - S_n\| \]
\[ = \sum_{j \geq 0} \|S_n\| |\hat{\lambda}_j| \left( \sum_{k \geq j+1} \frac{1}{k!} \right) \|R_n - S_n\| \]
\[ < (e-1)e^{\|S_n\|} \|R_n - S_n\| . \]

The estimate \( \|R_n^k - S_n^k\| \leq \sum_{j=0}^{k-1} \|S_n\| |\hat{\lambda}_j| \|R_n - S_n\| \) is easily established by induction. So \( \lim_{n \to \infty} \|U_n - V_n\| = 0. \)

Let \( M_k^n = U_n N_k^n. \) Then \( M_k^n = U_n V_n^{-1} N_k^n \), and since
\[ \lim_{n \to \infty} \|U_n V_n^{-1} - I\| = 0, \]

it follows that
\[ \lim_{n \to \infty} \sup_{1 \leq k \leq n} \|P(M_k^n) - P(N_k^n)\| = 0 . \]

Let \( W_n \) be another unitary carrying each \( N_k^n \) onto \( M_k^n, 1 \leq k \leq n. \) Then \( U_n W_n \) takes each \( N_k^n \) onto itself, as does \( W_n U_n. \) So \( U_n W_n \) belongs to \( T_n \cap T_n^* = D_n, \) the diagonal algebra (i.e. \( W_n = UD \) where \( D \) is a diagonal unitary). So
\[ \|W_n - I\| = \|U_n - D^*\| \geq \|\Delta(U_n) - D^*\| \]
\[ \geq \|\Delta(V_n) - D^*\| - \|U_n - V_n\| = \|I - D^*\| - \|U_n - V_n\| . \]

But since \( \|R_n\| = 1, \) the spectrum of \( U_n \) contains one of the \( e^{\pm i\theta}, \) and so
\[ \|U - I\| = |e^{i\theta} - 1| = 2\sin \frac{\theta}{2} . \] So
\[ \|U_n - D^*\| \geq \|U_n - I\| - \|D^* - I\| = 2\sin \frac{\theta}{2} - \|D^* - I\| . \]

Combining these two inequalities yields
\[ \|W_n - I\| \geq \sin \left( \frac{1}{2} \right) - \|U_n - V_n\| . \]

Identify \( \mathcal{H} \) with \( \sum_{n \geq n_0} \mathcal{Q}^n. \) Let \( \mathcal{P} \) be identified with the nest obtained by concatenating the nests \( \{N_k^n, 1 \leq k \leq n\} \) for \( n \geq n_0. \) Let \( U = \sum_{n \geq n_0} U_n, \) and \( \mathcal{Q} = U P. \) By construction, \( \mathcal{Q} \) is asymptotic to \( \mathcal{P} \) and
\[ \sup_{1 \leq k \leq n_0} \|P(Q_k) - P(P_k)\| \leq \sup_{n \geq n_0} 2\|U_n V_n^{-1} - I\| . \]

So for \( n_0 \) large, \( \mathcal{Q} \) and \( \mathcal{P} \) are both close and compactly perturbed. Suppose that \( W \) is a unitary carrying \( \mathcal{P} \) onto \( \mathcal{Q}. \) Then \( W \) carries each block \( \mathcal{Q}^n \) onto
itself. So \( W = \sum_{n \geq n_0} \oplus W_n \), and \( W_n \) carries \( \{N_n^k, 1 \leq k \leq n\} \) onto \( \{M^k_p, 1 \leq k \leq n\} \). As we have just seen,

\[
\lim_{n \to \infty} \|W_n - I\| = \sin\left(\frac{1}{2}\right) > 0.
\]

Notes and Remarks.

The notion of quasitriangularity was introduced by Halmos [3]. It is a key idea in the proof of a number of invariant subspace theorems. An important theorem of Apostol, Foias, and Voiculescu [1] characterizes quasitriangular operators as those operators \( T \) such that \( \text{ind}(T - \lambda I) \geq 0 \) whenever \( T - \lambda I \) is semi Fredholm. Most of Theorem 12.1 is due to Fall, Arveson and Muhly [1] with the exception that the quotient map \( \pi \) is isometric. The proof given here is from Davidson and Power [2]. Theorem 12.2 is due to Arveson [7]. Theorem 12.5 is in Fall, Arveson and Muhly. Theorem 12.6 is in Davidson and Power. Another proof that \( Q \neq \mathcal{T}(\mathcal{H}) \) is proximinal in \( \mathcal{B}(\mathcal{H}) \) is given by Feeman [1,2].

Theorem 12.8 is due to Andersen [1] and Davidson [6]. Andersen proved the equivalence of 1), 2) and 3). Davidson added 4). The approach given here is new in several ways. In particular, the use of \( M^p_{\mathcal{K}} \) to locate the atoms is taken from Apostol and Davidson [1]. Lemma 12.10 is a special case of a theorem in Davidson [1].

Exercises.

12.1 Let \( T \) be a quasitriangular operator and let \( \epsilon > 0 \) be given. Show there is a compact operator \( K \) with \( \|K\| < \epsilon \) and an orthonormal basis \( \{e_n, n \geq 1\} \) so that \( T - K \) is triangular with respect to this basis.

12.2 Use Theorem 12.2 to prove that if \( P = \{P_n, n \geq 1\} \) and \( Q = \{Q_n, n \geq 1\} \) are nests of finite rank projections with \( \sup P_n = \frac{1}{2} = \sup Q_n \) and \( \lim \|P_n - Q_n\| = 0 \), then \( Q \neq \mathcal{T}(P) = Q \neq \mathcal{T}(Q) \).

12.3 (i) Let \( X \) be a compact Hausdorff space. Use the Riesz Representation Theorem to show that the dual of \( C_0(X, K) \) is \( \mathcal{K}(X, C_1) \), the space of bounded regular Borel measures on \( X \) with values in \( C_1 \).

(ii) Show that a bounded net \( \Phi_n \) in \( C_0(X, \mathcal{B}(\mathcal{H})) \) converges to \( \Phi \) in the \( C_0(X, K)^* \) topology if and only if \( \Phi_n(x) \) converges weak* to \( \Phi(x) \) pointwise.

12.4 This example is designed to show that Lemma 12.14 fails if \( E_1 - F_1 \) is not compact. Let \( n \geq 4 \) be a positive integer, and let \( \mathcal{H} = \mathcal{H}_1 \oplus \ldots \oplus \mathcal{H}_n \), where \( \mathcal{H}_j \) are isomorphic Hilbert spaces. Let \( E_j \) be the projection onto \( \mathcal{H}_j \). Let \( Q(x_1, \ldots, x_n) = (\overline{x}, \overline{x}, \ldots, \overline{x}) \) where
\[ \overline{x} = \frac{1}{n} \sum_{i=1}^{n} x_i. \] Then \( Q \) is the orthogonal projection onto \( Q = \{ (x, \ldots, x) : x \in \mathcal{H}_1 \} \). Let \( S \) be the unilateral shift acting on \( Q \), and let \( V = Q^\perp + Q \). Define \( F_j = VE_jV^* \). Then \( \sum_{j=1}^{n} F_j = VV^* \) has codimension 1 while \( \sum_{j=1}^{n} E_j = I \). Prove that \( \| E_j - F_j \| \leq (\frac{4}{n})^n \) for \( 1 \leq j \leq n \).

12.5 Let \( \epsilon_n \) be positive numbers such that \( \prod_{n=1}^{\infty} (1 + \epsilon_n) = 1 + \epsilon \) exists. Let \( A_n \) be operators with \( \| A_n \| \leq \epsilon_n \). Define \( T_0 = I \) and \( T_n = (1 + A_n)T_{n-1} \). Prove that \( \| T_n - I \| \leq \prod_{k=1}^{n} (1 + \epsilon_k) - 1 \). Hence establish that \( T_n \) is Cauchy with a limit \( T \) such that \( \| T - I \| \leq \epsilon \).

12.6 Let \( \mathcal{H} \) be a nest and let \( A \) be an operator such that the range of \( \Phi_A(N) = P(N)^{-1}AP(N) \) is a norm compact subset of \( K \). Prove that \( A \) belongs to \( Q \mathcal{T}(\mathcal{H}) \). Hint: Compare the norm and strong* topologies on \( \text{Ran} \Phi_A \).

12.7 Let \( \mathcal{N} \) and \( \mathcal{M} \) be nests. Suppose that \( \alpha \) is an algebra isomorphism of \( Q \mathcal{T}(\mathcal{N}) \) onto \( Q \mathcal{T}(\mathcal{M}) \).

(i) Prove that \( \alpha \) carries the set of finite rank operators onto itself.

(ii) Show that there is an invertible operator \( S \) so that \( \alpha(F) = SFS^{-1} \) for all finite rank operators.

(iii) Deduce that \( \alpha(T) = STS^{-1} \) for all \( T \). Hence \( \alpha \) is continuous.

(iv) Show that \( \mathcal{N} \) ad \( \mathcal{M} \) have finite perturbations which are similar.

(v) (Plastiras) If \( \mathcal{N} = \{ N_k, k \geq 1, \mathcal{H} \} \) and \( \mathcal{M} = \{ M_k, k \geq 1, \mathcal{H} \} \) consist of finite dimensional subspaces with dense union and \( Q \mathcal{T}(\mathcal{N}) \) and \( Q \mathcal{T}(\mathcal{M}) \) are isomorphic, show that there are integers \( n_0 \) and \( k_0 \) so that

\[
\dim N_n = \dim M_{n+k_0}
\]

for all \( n \geq n_0 \).
13. Similarity and Approximate Unitary Equivalence

The main result of this chapter is the Similarity Theorem 13.20 which shows that two nests are similar if and only if there is a dimension preserving order isomorphism of one nest onto the other. This is quite different from the unitary invariants of chapter 7; for neither multiplicity nor the measure class need be preserved in general. Several examples will be given at the end to demonstrate some of the unusual phenomenon. In this chapter, all Hilbert spaces will be separable.

13.1. The first big step is to show that all continuous nests are approximately unitarily equivalent (Anderson's Theorem 13.9). Let $\mathcal{N}$ be a continuous nest $\{N_t, 0 \leq t \leq 1\}$ parametrized by $[0,1]$. Let $\theta$ be an order isomorphism of $\mathcal{N}$ onto another nest $\mathcal{M}$. Then $\mathcal{M}$ may be parametrized as $\{M_t, 0 \leq t \leq 1\}$ so that $\theta(N_t) = M_t$. Say that $\mathcal{N}$ and $\mathcal{M}$ are $\epsilon$-unitarily equivalent if there is a unitary $U$ such that $P(M_t)U - UP(N_t)$ is compact for all $0 \leq t \leq 1$, and

$$\sup_{0 \leq t \leq 1} \|P(M_t)U - UP(N_t)\| < \epsilon .$$

Now consider a method for decomposing a nest $\mathcal{N}$. Let $P$ be a projection in $\mathcal{N}$. Let $\mathcal{N}_1$ and $\mathcal{N}_2$ be the nests

$$\mathcal{N}_1 = \{N_t^{(1)} = N_t \cap P\mathcal{N} : 0 \leq t \leq 1\}$$

and

$$\mathcal{N}_2 = \{N_t^{(2)} = N_t \cap P^\perp\mathcal{N} : 0 \leq t \leq 1\} .$$

It is quite possible that the parametrization of $\mathcal{N}_1$ or $\mathcal{N}_2$ may be redundant. Indeed, $N_t^{(1)} = N_t^{(1)}$ precisely if $N_t \ominus N_t$ is orthogonal to $P$. We will write $\mathcal{N} \cong \mathcal{N}_1 \oplus \mathcal{N}_2$. More generally, if $\mathcal{N}_k$ are nests parametrized in $[0,1]$, the direct sum $\sum_{k \geq 1} \mathcal{N}_k$ will mean the nest $\mathcal{N}$ with elements $N_t \cong \sum_{k \geq 1} \oplus N_t^{(k)}$. The nests $\mathcal{N}_k$ are called *summands* of $\mathcal{N}$.

Let $E_{\mathcal{N}}$ denote the spectral measure of $\mathcal{N}$ introduced in Corollary 7.6. Given a vector $x$ in $\mathcal{N}$, define the *support* of $x$ (supp($x$)) to be the smallest closed subset $C$ of $[0,1]$ such that $E_{\mathcal{N}}(C)x = x$. If $\mathcal{N}_1$ is a summand of $\mathcal{N}$, then supp($\mathcal{N}_1$) is the smallest closed set $C$ such that $E_{\mathcal{N}}(C)x = x$ for all $x$ in $N_1^{(1)}$. In particular, if $\mathcal{N}_1$ has a cyclic vector $x_1$ (meaning that $\span\{P(N_1^{(1)}x_1 = N_1^{(1)}\}$, then supp($\mathcal{N}_1$) = supp($x_1$).
13.2 Lemma. Let $\mathcal{N}$ be a continuous nest, and let $J_i$ be open subset of $J_0 = (0,1)$ for $i \geq 0$. Then $\mathcal{N}$ has pairwise orthogonal summands $\mathcal{N}_i$ with support $J_i$ such that $\mathcal{N} \cong \bigoplus_{i=0}^{\infty} \mathcal{N}_i$. If $\mathcal{N}$ is cyclic, so is each $\mathcal{N}_i$.

Proof. Let $\mu$ be a finite regular Borel measure on $[0,1]$ mutually absolutely continuous to the spectral measure $E_{\mathcal{N}}$. (For example, $\mu(A) = (E_{\mathcal{N}}(A) x, x)$ where $x$ is a separating vector for $\mathcal{N}^0$.) Since $\mathcal{N}$ is continuous, $\mu$ is non-atomic. It is an exercise in measure theory to produce disjoint Borel sets $A_i$ contained in $J_i$ such that $J_0 = \bigcup_{i \geq 0} A_i$ and $\mu(A_i \cap I) > 0$ for every open set $I$ of $J_i$ (see Exercise 13.2). Set $\mathcal{N}_i = \mathcal{N} | E_{\mathcal{N}}(A_i) \mathcal{N}$. It follows that the support of $\mathcal{N}_i$ is $\overline{A_i} = J_i$, and $\mathcal{N} \cong \bigoplus_{i \geq 0} \mathcal{N}_i$. If $x$ is cyclic for $\mathcal{N}$, then $x_i = E(A_i)x$ is cyclic for $\mathcal{N}_i$.

The next lemma shows that every continuous nest has "approximate infinite multiplicity" in a certain sense.

13.3 Lemma. Let $\mathcal{N}$ be a continuous nest. Then $\mathcal{N} \cong \bigoplus_{i=1}^{\infty} \mathcal{N}_i$ where each $\mathcal{N}_i$ is cyclic with support $[0,1]$.

Proof. For each non-zero vector $x$, let $\mathcal{H}_x$ denote the closed span of $\{P(N)x : N \in \mathcal{N}\}$. The projection onto $\mathcal{H}_x$ commutes with $\mathcal{N}$, and $\mathcal{H}_x = \mathcal{N} | \mathcal{H}_x$ has $x$ as a cyclic vector. By Proposition 2.12, there is a separating vector $x_0$ for $\mathcal{N}^0$. Clearly, $\text{supp}(x_0) = [0,1]$. Extend $\{x_0\}$ to a maximal (countable or finite) family $\{x_n, 0 \leq n < \alpha\}$ of non-zero vectors such that $\mathcal{H}_{x_n}$ are pairwise orthogonal. The maximality guarantees that $\mathcal{N}$ is the direct sum $\bigoplus \mathcal{H}_{x_n}$. Let $C_n = \text{supp}(x_n)$.

Let $J_n = (0,1) \setminus C_n$ for $1 \leq n < \alpha$. Since $C_0 = [0,1]$, one may apply Lemma 13.2 to $\mathcal{N}_0$ to obtain a decomposition

$$\mathcal{H}_{x_n} \cong \bigoplus_{1 \leq n < \alpha} \mathcal{M}_n \bigoplus \bigoplus_{j=1}^{\infty} \mathcal{L}_j$$

where $\text{supp}(\mathcal{M}_n) = \overline{J_n}$ and $\text{supp}(\mathcal{L}_j) = [0,1]$ for $j \geq 1$. Since $\mathcal{N}_0$ has a cyclic vector $x_0$, each summand is cyclic. Let $y_n$ be a cyclic vector for $\mathcal{M}_n$, $1 \leq n < \alpha$ and $z_j$ be a cyclic vector for $\mathcal{L}_j$, $j \geq 1$.

Notice that if $x$ and $y$ have supports $S_1$ and $S_2$ satisfying $E_{\mathcal{N}}(S_1 \cap S_2) = 0$, then $\mathcal{N}_{x+y} = \mathcal{N}_x \oplus \mathcal{N}_y$ and $\text{supp}(x+y) = S_1 \cup S_2$. Let $w_n = x_n + y_n$ for $1 \leq n < \alpha$. By construction, $\mathcal{N}_{w_n} \cong \mathcal{N}_{x_n} \oplus \mathcal{N}_n$ and $\text{supp}(w_n) = [0,1]$. So
\[ \mathcal{N} \cong M_{z_0} \oplus \bigoplus_{n=1}^{\infty} \bigoplus_{j=1}^{\infty} M_{z_j} \]
\[ \cong \bigoplus_{n=1}^{\infty} M_n \oplus \bigoplus_{n=1}^{\infty} L_j \]

Consequently, \( \mathcal{N} \) is the direct sum of countably many cyclic nests with support \([0,1]\).

Next, we wish to construct a sequence \( F_n \) of positive finite rank contractions converging strongly to the identity operator such that \( \sup \{ \| F_n - P(N) F_n \| : N \in \mathcal{N} \} \) tends to zero as \( n \) increases. This will be called a quasi-central approximative identity.

**13.4 Lemma.** Let \( y_j, z_j, 1 \leq j < L \) be vectors such that \( \| y_i \| \leq 1 \), \( \| z_j \| \leq 1 \), and \( \max_{i < j} \| (y_i, y_j)_L (z_i, z_j)_L \| < 1/L^2 \). Then \( \| \sum_{j=1}^{L} y_j \otimes z_j^* \| \leq 2 \).

**Proof.** Let \( e_1, \ldots, e_L \) be an orthonormal set. Let \( A = \sum_{j=1}^{L} y_j \otimes e_j^* \) and \( B = \sum_{j=1}^{L} e_j \otimes z_j^* \). Then \( A B = \sum_{j=1}^{L} y_j \otimes z_j^* \).

\[
\| A \| = \| A^* A \| = \| \sum_{i=1}^{L} \sum_{j=1}^{L} (y_j, y_i) e_i \otimes e_j^* \|
\leq \max_{1 \leq j \leq L} |(y_j, y_i)| + \sum_{i \neq j} |(y_j, y_i)| \leq 1 + L^2/L^2 = 2.
\]

Similarly, \( \| B \| \leq 2 \). So \( \| \sum_{j=1}^{L} y_j \otimes z_j^* \| \leq \| A \| \| B \| \leq 2 \).

**13.5 Lemma.** Let \( \mathcal{N} \) be a continuous nest with cyclic vector \( x \). Let \( E_{\mathcal{N}} \) be the spectral measure for \( \mathcal{N} \), and set \( E_{k, n} = E_{\mathcal{N}} \left( \frac{k-1}{2^n}, \frac{k}{2^n} \right) \) for \( 1 \leq k \leq 2^n \). Let \( x_{k,n} = \| E_{k, n} x \|^{-1} E_{k, n} x \), and let \( P_n \) be the projection onto \( \text{span} \{ x_{k,n} : 1 \leq k \leq 2^n \} \). Given \( n \geq 1 \) and \( \epsilon > 0 \), there is a finite rank positive contraction \( F \geq P_n \) which is a convex combination of \( \{ P_m, m \geq n \} \) such that \( \sup_{0 \leq t \leq 1} \| P(N_t) F - F P(N_t) \| < \epsilon \).
Proof. Let \( f(t) = \| P(N_t)x \|^2 \), and note that this is a strictly increasing continuous function of \([0,1]\) onto itself. From the uniform continuity of \( f \), one obtains
\[
\lim_{n \to \infty} \max_{1 \leq k \leq 2^n} \| E_{k,n} x \|^2 \leq \lim_{n \to \infty} \sup_{|t| \leq 2^{-n}} | f(s) - f(t) | = 0.
\]
For \( m = n + p \), one has
\[
x_{k,n} = \sum_{j = 2^{q(k-1)+1}}^{2^{q(k-1)+1}} a_j x_{j,m}
\]
where
\[
a_j = (x_{k,n}, x_{j,m}) = \| E_{k,n} x \|^{-1} \| E_{j,m} x \|^{-1} \| E_{j,m} x \|^2 = \| E_{k,n} x \|^{-1} \| E_{j,m} x \|.
\]
Let
\[
\delta(n,m) = \max_{1 \leq j \leq 2^m} a_j \leq \max_{1 \leq k \leq 2^n} \| E_{k,n} x \|^{-1} \max_{1 \leq j \leq 2^m} \| E_{j,m} x \|.
\]
Then \( \lim_{m \to \infty} \delta(n,m) = 0 \) for any fixed \( n \).

Let \( L = 2(\epsilon^{-1}+1) \), and choose integers \( n = m_1 < m_2 < \ldots < m_L \) so that \( \delta(m_j, m_{j+1}) < 1/L^2 \) for \( 1 \leq j \leq L \). Set \( F = L^{-1} \sum_{j=1}^{L} P_{m_j} \). Fix \( t \) in \([0,1]\) and compute \( [P(N_t), F] = P(N_t) F - F P(N_t) \). For each \( j \), there is an integer \( k_j \) such that \( k_j - 1 \leq 2^m t \leq k_j \). Now
\[
P_{m_j} = \sum_{k=1}^{2^{m_j}} x_{k,m_j} \otimes x_{k,m_j}^*.
\]
If \( k \neq k_j \), then \( P(N_t) \) commutes with \( x_{k,m_j} \otimes x_{k,m_j}^* \). So
\[
[P(N_t), P_{m_j}] = [P(N_t), x_{k_j,m_j} \otimes x_{k_j,m_j}^*] = y_j \otimes z_j^* \otimes y_j^*.
\]
where \( y_j = P(N_t) x_{k_j,m_j} \) and \( z_j = P(N_t)^{-1} x_{k_j,m_j} \). So
\[
[P(N_t), F] = L^{-1} \sum_{j=1}^{L} y_j \otimes z_j^* \otimes y_j^*.
\]
If \( i < j \), then
\[
|\langle y_i, y_j \rangle| + |\langle z_i, z_j \rangle| = (x_{k_i,m_i}, x_{k_j,m_j}) \leq \delta(m_i, m_j) < 1/L^2.
\]
Hence by Lemma 13.4,
\[
\| [P(N_t), F] \| = L^{-1} \max \| \sum_{j=1}^{L} y_j \otimes z_j^* \| \| \sum_{j=1}^{L} x_j \otimes y_j^* \| \leq 2L^{-1} < \epsilon.
\]
Now, this quasi-central approximate unit will be used to approximately embed $N$ as a summand of another continuous nest $M$.

13.6 Lemma. Let $N$ and $P_n$ be as in Lemma 13.5. Let $M$ be another continuous nest with cyclic vector $y$. Given an integer $n_0$, and an $\epsilon > 0$, there is a unitary operator $U$ such that

$$\sup_{0 \leq t \leq 1} \| (P(M_t)U - UP(M_t))P_{n_0} \| < \epsilon .$$

Proof. Let $x_{k,n}$ be defined as in Lemma 13.5. Similarly, define unit vectors $y_{k,n}$ for $M$. Choose $n > n_0$ sufficiently large so that $\delta(n_0,n) < \epsilon/2$. Define $U$ by setting $Ux_{k,n} = y_{k,n}$ for $1 \leq k \leq 2^n$ and extending it in such a way that

$$UE_{M} \left( \frac{k-1}{2^n}, \frac{k}{2^n} \right) = EM \left( \frac{k-1}{2^n}, \frac{k}{2^n} \right), \quad 1 \leq k \leq 2^n .$$

Fix $t$ in $[0,1]$, and choose integers $k$ and $i$ so that

$$k-1 \leq 2^n t \leq k \quad \text{and} \quad i-1 \leq 2^n t \leq i .$$

Then $P(M_t)Ux_{j,n} = UP(M_t)x_{j,n}$ for $j \neq i$. So in particular, $P(M_t)U - UP(M_t)x_{k,n_0} = 0$ for $k \neq k$. Write $x_{k,n_0} = \sum a_j x_{j,n}$. Then

$$\| (P(M_t)U - UP(M_t))P_{n_0} \| = \| (P(M_t)U - UP(M_t))x_{k,n_0} \|$$

$$= |a_i| \| (P(M_t)U - UP(M_t))x_{i,n} \|$$

$$\leq 2\delta(n_0,n) < \epsilon . \quad \Box$$

13.7 Lemma. Let $E$ be a positive operator, and let $T$ be an operator with $\| T \| \leq 1$. Then $\| [E^k, T] \| \leq \sqrt{2} \| [E, T] \|^k$.

Proof. Note that for any operators $A$ and $B$ that

$$\| [A^n, B] \| = \| \sum_{k=0}^{n-1} A^k [A, B] A^{n-1-k} \| \leq n \| [A] \| \| [A, B] \| .$$

Now consider the power series

$$f(t) = 1 - (1-t)^n = \sum_{n \geq 1} a_n t^n, \quad |t| < 1$$

where $a_n = \frac{(-1)^{n-1}}{n!} \prod_{k=0}^{n-1} \left( \frac{1}{2} - k \right) > 0$ for all $n \geq 1$. Differentiating yields

$$f'(t) = 2^{-1} (1-t)^{-n} = \sum_{n \geq 1} n a_n t^{n-1} .$$

Normalize $E$ so that $\| E \| = 1$. (This doesn't affect the relationship in the lemma.) For $0 < \delta < 1$, set $A = (1-\delta)I - E = I - (E + \delta I)$. Then
\[(E+\delta I)^k = I - f(A),\] whence
\[
\|\|[(E+\delta I)^k,T]\|\| = \|\| \sum_{n \geq 1} a_n A^n T \|\| \leq \sum_{n \geq 1} a_n n \|A\|^{n-1} \|A,T\| \\
= f'(\|A\|) \|E,T\| \leq f'(1-\delta) \|E,T\| \\
= \frac{\|E,T\|}{2\delta^k}. 
\]

On the other hand,
\[
0 \leq (E+\delta I)^k - E^k = \delta((E+\delta I)^k + E^k)^{-1} \leq \delta^k I.
\]

So
\[
\|\|E^k,T\|\| \leq \|\|(E+\delta I)^k,T\|\| + \|\|(E+\delta I)^k - E^k - \frac{\delta}{2} \delta^k I,T\|\| \\
\leq \|\|E,T\|\|/2\delta^k + 2\|\|(E+\delta I)^k - E^k - \frac{\delta}{2} \delta^k I\|\| \|T\|\| \\
\leq \|\|E,T\|\|/2\delta^k + \delta^k \|T\|\|
\]

Set \(\delta\) so that \((2\delta)^k = \|\|E,T\|\|^k \|T\|^{1-k}.\) Then
\[
\|\|E^k,T\|\| \leq \sqrt{2} \|\|E,T\|\|^k \|T\|^{1-k}.
\]

13.8 Lemma. Let \(\mathcal{M}\) be a continuous nest, and let \(\mathcal{N}\) be a continuous nest with cyclic vector. Given \(\epsilon > 0\), there is an isometry \(U\) such that \(f(t) = P(M_t)U - U P(N_t)\) is norm continuous, and compact of norm at most \(\epsilon\) for all \(0 \leq t \leq 1\) (i.e. \(f \in C_0(\mathcal{M},\mathcal{K})\) and \(\|f\| \leq \epsilon\)).

Proof. By Lemma 13.3, \(\mathcal{M}\) can be decomposed as \(\mathcal{M} = \bigoplus_{j=1}^\infty \mathcal{M}_j\) on \(\mathcal{K} = \bigoplus_1^\infty \mathcal{K}_j\) where each \(\mathcal{M}_j\) has a cyclic vector \(y_j\) with support \([0,1]\).

Let \(P_n\) be defined as in Lemma 13.5 for \(\mathcal{M}\). Recursively choose integers \(n_k\), positive finite rank contractions \(F_k\), and unitaries \(U_k\) of \(\mathcal{K}\) into \(\mathcal{K}\) so that \(n_0 = 0, n_1 = 1, F_0 = 0\) and

1) \(P_{n_k} \leq F_k \leq P_{n_{k+1}}\)
2) \(\sup_{0 \leq i \leq k} \|P(N_i)F_k - F_k P(N_i)\| < (\epsilon/2^{k+1})^2/10.\)
3) \(\sup_{0 \leq i \leq k} \|P(M_i)U_k - U_k P(N_i)\| P_{n_{k+1}} < 2^{-k-1}\epsilon.\)

This is done as follows: given \(n_k, F_{k-1}\) and \(U_{k-1}\), use Lemma 13.5 to obtain \(F_k\) satisfying \(F_k \geq P_{n_k}\) and ii). Then \(n_{k+1}\) is chosen to satisfy i). Now Lemma 13.6 is used to obtain \(U_k\) satisfying iii).

Define \(E_k = (F_k - F_{k-1})^k\) for \(k \geq 1\), and \(U = \sum_{k=1}^\infty U_k E_k\). Since the \(U_k\) have orthogonal ranges,
\[ U^*U = \sum_{k=1}^{\infty} E_k^2 = I \]

and thus \( U \) is an isometry. Also, by Lemma 13.7

\[
\| E_k P(N_t) - P(N_t) E_k \| \leq \sqrt{2} \| [F_k - F_{k-1}, P(N_t)] \|^{1/2} \\
\leq \sqrt{2} \left( \frac{\epsilon/2^k}{10} + \frac{\epsilon/2^{k+1}}{10} \right)^{1/2} \\
= \frac{\epsilon}{2^{k+1}} .
\]

Thus

\[
\| P(M_t) U - UP(N_t) \| = \sum_{k=1}^{\infty} \left( \| P(M_t) U_k - U_k P(N_t) \| E_k \right) \\
+ \| U_k [P(N_t), E_k] \| \\
\leq \sum_{k=1}^{\infty} \left( \| (P(M_t) U_k - U_k P(N_t)) E_{k+1} \| \\
+ \| [P(N_t), E_k] \| \right) \\
< \sum_{k=1}^{\infty} 2^{-k-1} \epsilon + 2^{-k-1} \epsilon = \epsilon .
\]

Furthermore, this is a convergent sum of finite rank operators, and thus is compact. The strong continuity of \( t \to P(M_t) \) and \( t \to P(N_t) \) guarantees that each term is norm continuous. The limit is uniform in \( t \), and hence is also norm continuous. \( \blacksquare \)

### 13.9 Andersen's Theorem

Let \( \mathcal{H} \) and \( \mathcal{M} \) be continuous nests on a separable Hilbert space, and let \( \theta \) be an order isomorphism of \( \mathcal{H} \) onto \( \mathcal{M} \). Given \( \epsilon > 0 \), there is a unitary operator \( U \) such that \( f(N) = P(\theta(N)) - WP(N)W^* \) is continuous, compact valued and of norm at most \( \epsilon \) for all \( N \) in \( \mathcal{H} \).

**Proof.** Parametrize \( \mathcal{H} \) as \( \{N_t, 0 \leq t \leq 1\} \) and \( \mathcal{M} \) as \( \{M_t, 0 \leq t \leq 1\} \) so that \( \theta(N_t) = M_t \). Apply Lemma 13.3 to decompose \( \mathcal{M}^{(\infty)} \), the direct sum of countably many copies of \( \mathcal{H} \), as \( \mathcal{M}^{(\infty)} \cong \bigoplus_{i=1}^{\infty} \mathcal{H}_i \) on \( \mathcal{H}^{(\infty)} \cong \bigoplus_{i=1}^{\infty} \mathcal{H}_i \) where each \( \mathcal{H}_i \) is cyclic with support \([0, 1]\). Likewise, decompose \( \mathcal{M} \cong \bigoplus_{i=1}^{\infty} \mathcal{M}_i \) on \( \mathcal{H}' = \bigoplus_{i=1}^{\infty} \mathcal{H}_i' \). By Lemma 13.8, there are isometries \( U_i \) of \( \mathcal{H}_i \) into \( \mathcal{H}_i' \) so that \( f_i(t) = P(M_t) U_i - U_i P(N_t) \) belongs to \( C_0(\mathcal{M}, K) \) and \( \| f_i \| \leq 2^{-i} \epsilon \). Thus \( U = \bigoplus_{i=1}^{\infty} U_i \) is an isometry of \( \mathcal{H} \) into \( \mathcal{H}' \) such that

\[
f(t) = P(M_t) U - UP(N_t) \]

belongs to \( C_0(\mathcal{H}, K) \) and \( \| f \| \leq \sum_{i \geq 1} \| f_i \| \leq \epsilon .\)
Let \( P \) be the projection \( P = UU^* \), and compute:
\[
P(M_t)P - PP(M_t) = (P(M_t)U - UP(N_t^{(o)}))U^* - U(P(M_t)U - UP(N_t^{(o)}))
\]
Thus \( t \to [P(M_t), P] \) is continuous, and compact of norm at most \( 2\epsilon \) for all \( 0 \leq t \leq 1 \). This produces an "approximate summand" of \( \mathcal{M} \) unitarily equivalent to \( \mathcal{M}^{(o)} \). If one proceeds formally, one obtains a "complement" \( L \) of \( \mathcal{M}^{(o)} \) in \( \mathcal{M} \). A formal computation yields
\[
\mathcal{M} \sim L \oplus \mathcal{M}^{(o)} \cong (L \oplus \mathcal{M}^{(o)}) \oplus \mathcal{M} \sim \mathcal{M} \oplus \mathcal{M} \mathcal{N}.
\]
To make this precise, let \( S \) be the shift on \( \mathcal{M}^{(o)} \) given by
\[
S(x_1, x_2, \ldots) = (0, x_1, x_2, \ldots)
\]
and let \( J \) be the isometry of \( \mathcal{N} \) into \( \mathcal{M}^{(o)} \) given by \( Jz = (x, 0, 0, \ldots) \). Define a unitary \( W \) of \( \mathcal{N}^{(o)} \oplus \mathcal{N} \) onto \( \mathcal{N}^{(o)} \) by \([P \perp + USU^* UJ]\). Use the facts that \( S \) commutes with \( P(N_t^{(o)}) \) and \( P(N_t^{(o)})J = JP(N_t) \) to compute \( P(M_t)W = W(P(M_t) + P(N_t)) \). The first matrix entry is
\[
P(M_t)P_{\perp} + P(M_t)USU^* - P_{\perp}P(M_t) - USU^*P(M_t) =
\]
\[
= [P(M_t), P_{\perp}] + (P(M_t)U - UP(N_t^{(o)}))SU^* + US(UP(N_t^{(o)}) - P(M_t)U)^*
\]
which is continuous in \( t \), compact, and has norm at most \( 4\epsilon \). The second matrix entry is
\[
P(M_t)UJ - UJP(N_t) = (P(M_t)U - UP(N_t^{(o)}))J
\]
which is continuous and compact with norm at most \( \epsilon \). Hence \( P(M_t)W = W(P(M_t) + P(N_t)) \) is continuous and compact with norm at most \( 5\epsilon \).

Reversing the roles of \( \mathcal{N} \) and \( \mathcal{M} \) yields another unitary \( W' \) such that \( (P(M_t) + P(N_t))W' = WP(N_t) \) is continuous and compact valued and has norm at most \( 5\epsilon \). So \( t \to P(M_t)WW' - WW'P(N_t) \) is continuous, compact and of norm at most \( 10\epsilon \).

Combining this result with Theorem 12.8 yields:

13.10 Theorem. Let \( \mathcal{N} \) and \( \mathcal{M} \) be continuous nests on a separable Hilbert space. Let \( \theta \) be any order isomorphism of \( \mathcal{N} \) onto \( \mathcal{M} \), and let \( \epsilon > 0 \) be given. Then there is an invertible operator \( S = U + K \) where \( U \) is unitary, \( K \) is compact, and \( \|K\| < \epsilon \) such that \( S\mathcal{N} = \mathcal{M} \) and \( \theta_S = \theta \).

Proof. By Theorem 13.9, there is a unitary \( U \) such that \( U\mathcal{N} \) and \( \mathcal{M} \) are compactly perturbed nests via the isomorphism \( \theta \circ \theta_U^{-1} \). So by Theorem 12.8 and the norm estimate of Theorem 12.18, the invertible operator \( S \) exists as required.
13.11 Example. It is an immediate consequence of this theorem that neither multiplicity nor measure class is preserved by similarity. For example, let \( \mathcal{N} \) be the Volterra nest \( \{ N_t : 0 \leq t \leq 1 \} \) of functions in \( L^2([0,1]) \) supported on \([0,t], 0 \leq t \leq 1 \). Let \( \mathcal{M} \) be the nest of Example 1.6 on \( L^2([0,1]^2) \) given by \( M_t \), the subspace of functions supported on \([0,t] \times [0,1] \) for \( 0 \leq t \leq 1 \). Then \( \mathcal{M} \) has infinite multiplicity since \( \mathcal{M}' \) has uniform infinite multiplicity, whereas \( \mathcal{N}' \) is maximal abelian and so \( \mathcal{N} \) has multiplicity one. By Theorem 13.10, these two nests are similar.

13.12 Example. Now let \( h \) be an order preserving homeomorphism of \([0,1] \) onto itself, and consider the automorphism of \( \mathcal{N} \) given by \( \theta(N_t) = N_{h(t)} \). The scalar spectral measure for \( \theta(\mathcal{N}) \) is equivalent to the Lebesgue-Stieltjes measure \( dh \). By Theorem 7.16, there is a unitary operator \( U \) such that \( UN_t = N_{h(t)} \) for every \( t \) in \([0,1] \) precisely when \( dh \) is mutually absolutely continuous with Lebesgue measure. However, even if \( dh \) is singular to Lebesgue measure, there is an invertible operator \( S \) so that \( SN_t = N_{h(t)} \).

13.13 Example. Let \( V \) be the Volterra operator. By Theorem 5.5, \( \text{Lat}(V) \) equals \( \mathcal{N} \). Let \( S \) be the invertible operator guaranteed in Example 13.11 such that \( S\mathcal{N} = \mathcal{M} \). Then \( S\mathcal{N}S^{-1} \) is a compact operator such that \( \text{Lat}(S\mathcal{N}S^{-1}) = \mathcal{M} \). So, although \( S\mathcal{N}S^{-1} \) has a maximal nest of invariant subspaces, it does not have a multiplicity free nest of invariant subspaces.

An operator with a multiplicity free nest of invariant subspaces has been called hyperintransitive. The example above shows that not every compact operator has this property. However:

13.14 Corollary. Every compact operator \( K \) is similar to an operator with a multiplicity free nest of invariant subspaces.

Proof. By Corollary 3.2, \( K \) has a maximal nest \( \mathcal{N} \) of invariant subspaces. Thus all the atoms of \( \mathcal{N} \) are one dimensional. Let \( P \) be the projection onto the span of all atoms of \( \mathcal{N} \). Then \( \mathcal{N} | P^\perp \mathcal{N} \) is a continuous nest. By Theorem 13.10, there is an invertible operator \( S \) of \( P^\perp \mathcal{N} \) onto \( L^2([0,1]) \) such that \( S(\mathcal{N} | P^\perp \mathcal{N}) \) is the Volterra nest. Hence \( T = P + SP^\perp \mathcal{N} \) is an invertible operator of \( \mathcal{N} \) onto \( P\mathcal{N} \oplus L^2([0,1]) \) such that \( T\mathcal{N} \) is multiplicity free. So \( TKT^{-1} \) is hyperintransitive.

A refinement of this is to take any \( \epsilon > 0 \) and choose \( S = U + L \) where \( U \) is unitary, \( L \) is compact, and \( \| L \| < \epsilon \). Then \( T_\epsilon = P + U^*SP^\perp \mathcal{N} \) satisfies \( \| T_\epsilon - I \| < \epsilon \) and \( T_\epsilon KT_\epsilon^{-1} \) is hyperintransitive. So \( K \) is the limit of hyperintransitive operators similar to \( K \).
13.15. Now we turn to arbitrary nests. A typical nest to keep in mind is Example 2.6 of the canonical atomic nest $Q$ on $\ell^2(\mathbb{Q})$. This nest is order isomorphic to the Cantor set (section 2.14). Let $\mathcal{H}$ be the usual continuous nest on $L^2(\mathbb{R})$ given by the subspaces $N_t$ of functions supported on $(-\infty,t]$. The nest $\mathcal{K}$ given by $Q_t^+ \oplus N_t$ for $t \in \mathcal{K}$ is also order isomorphic to the Cantor set. The map $\theta$ of $Q$ onto $\mathcal{K}$ sending $Q_t^+$ to $Q_t^+ \oplus N_t$ is a dimension preserving, order isomorphism. But $Q$ and $\mathcal{K}$ are not unitarily equivalent since $Q$ is atomic and $\mathcal{K}$ has a continuous part.

An invertible operator $T$ is said to act absolutely continuously on a nest $\mathcal{H}$ if the spectral measure of $E_{T\mathcal{H}}$ is absolutely continuous with respect to $E_{\mathcal{H}}$ (where the order isomorphism between $\mathcal{H}$ and $T\mathcal{H}$ is taken to be $\theta_T$). Otherwise, it is said to act discontinuously, or even singularly in the event that $E_{T\mathcal{H}}$ is singular to $E_{\mathcal{H}}$. Recall from section 8.13 that a partition of $\mathcal{H}$ is a possibly infinite collection of intervals $\{E_\alpha\}$ of $\mathcal{H}$ and that $\sum E_\alpha = I$.

13.16 Lemma. Let $\mathcal{H}$ be a nest, and let $T$ be an invertible operator. If $E = P(N) - P(N^c)$ is an interval of $\mathcal{H}$, let $\hat{E} = P(TN) - P(TN^c)$. Then $T$ acts absolutely continuously on $\mathcal{H}$ if and only if for every partition $\{E_\alpha\}$, the corresponding intervals $\{\hat{E}_\alpha\}$ forms a partition of $TN$.

Proof. Suppose that $T$ acts absolutely continuously. Fix a homomorphism of $\mathcal{H}$ onto a subset $\omega$ of $[0,1]$, and let $E_{\mathcal{H}}$ be the associated spectral measure on $[0,1]$. For each $\alpha$, there are $N^\alpha_\alpha < N_\alpha$ in $\mathcal{H}$ and $a_\alpha < b_\alpha$ in $[0,1]$ such that

$$E_\alpha = P(N_\alpha) - P(N^\alpha_\alpha) = E_{\mathcal{H}}(a_\alpha, b_\alpha).$$

Also,

$$\hat{E}_\alpha = P(TN_\alpha) - P(N^\alpha_\alpha) = E_{T\mathcal{H}}(a_\alpha, b_\alpha).$$

Let $\delta = [0,1] \setminus \bigcup \{a_\alpha, b_\alpha\}$. Since $\{E_\alpha\}$ is a partition, $\sum E_\alpha = I$ and thus $E_{\mathcal{H}}(\delta) = 0$. By absolute continuity, $E_{T\mathcal{H}}(\delta) = 0$. So

$$\sum \hat{E}_\alpha = E_{T\mathcal{H}}([0,1] \setminus \delta) = I.$$

Conversely, suppose that $T$ preserves partitions. Let $\delta$ be a closed set such that $E_{\mathcal{H}}(\delta) = 0$. The complement $[0,1] \setminus \delta$ is a countable union of intervals $(a_n, b_n)$. Each $E_n = E_{\mathcal{H}}(a_n, b_n)$ is an interval of $\mathcal{H}$. Also, $\{E_n\}$ is a partition since $\sum E_n = I - E_{\mathcal{H}}(\delta) = I$. Since $T$ preserves partitions,

$$E_{T\mathcal{H}}(\delta) = I - \sum E_{T\mathcal{H}}(a_n, b_n) = I - \sum \hat{E}_n = 0.$$

The spectral measures $E_{\mathcal{H}}$ and $E_{T\mathcal{H}}$ are regular Borel measures, thus $E_{\mathcal{H}}(\delta) = 0$ implies $E_{T\mathcal{H}}(\delta) = 0$ for every Borel set $\delta$. Thus $T$ acts absolutely continuously. □
13.17 Lemma. Let $\mathcal{N}$ be an uncountable nest order equivalent to a subset $\omega$ of $[0,1]$. Then $\mathcal{N}$ has a partition $E_{11}E_{21}...$ into infinite dimensional intervals $E_n = E_{\mathcal{N}}(a_n,b_n)$ such that $\omega \setminus \bigcup_{n=1}^{\infty} (a_n,b_n)$ is uncountable.

Proof. First, it will be shown that any subset of $K$ of $[0,1]$ homeomorphic to the Cantor set contains a Cantor set $C$ such that every component of $[0,1]\setminus C$ has uncountable intersection with $K$. There is no loss of generality in letting $K$ be the usual Cantor set. Let $f$ be the Cantor function - a continuous non-decreasing function of $K$ onto $[0,1]$ which is one to one except on a countable set. Let $K'$ be a Cantor subset of $[1/3,2/3]$ which does not meet any of the countable many multiple image points. Then $C = f^{-1}(K')$ is a Cantor subset of $K$. The complement $[0,1]\setminus K'$ is a disjoint union $\bigcup_{n=1}^{\infty} J_n$ of open intervals. The complement of $C$ in $[0,1]$ is the disjoint union of intervals $I_n$ such that $I_n \cap K = f^{-1}(J_n)$ is uncountable.

Let $\mu$ be a scalar spectral measure for $\mathcal{N}$ on $\omega$. Since $\omega$ is uncountable, it contains a Cantor set $K$ such that $\mu(K) = 0$. (For example, let $L$ be any Cantor subset of $\omega$ disjoint from the (countable) set of atoms of $\mu$. If $\mu(L) \neq 0$, then $\mu [L]$ is a continuous measure. The usual “middle thirds” argument using the function $g(x) = \mu([0,x]\cap L)/\mu(L)$ yields a Cantor subset of $L$ of $\mu$-measure zero.) Inside $K$, choose a Cantor set $C$ as in the first paragraph. Let $[0,1]\setminus C$ be $\bigcup I_n$ where $I_n$ are the components of the complement. Then $E_n = E_{\mathcal{N}}(I_n)$ forms a partition of $\mathcal{N}$ since $E_{\mathcal{N}}(C) = 0$, and since $I_n \cap \omega$ is uncountable, each $E_n$ is infinite dimensional.

13.18 Lemma. Let $\mathcal{N}$ be an uncountable nest. Given $\epsilon > 0$, there is a positive, invertible operator $T$ such that $T-I$ is compact, $\|T-I\| < \epsilon$, and $T$ acts discontinuously on $\mathcal{N}$.

Proof. Let $E_n$ be the partition given by Lemma 13.17, where $E_n = E_{\mathcal{N}}(a_n,b_n)$ and $C = \omega \setminus \bigcup_{n=1}^{\infty} (a_n,b_n)$ is uncountable. By Lemma 13.16 it suffices to obtain an invertible operator $T$ which does not preserve the partition $E_n$. We construct a continuous nest $\mathcal{M}$ which also has $E_n$ as a partition. To this end, let $m$ be Lebesgue measure on $\bigcup_{n=1}^{\infty} (a_n,b_n)$. Let $\mathcal{M}'$ be the continuous nest in $L^2(m)$ given by subspaces $\mathcal{M}'_t$ of functions supported on $[0,t]$. Let $U$ be a unitary of $L^2(m)$ onto $\mathcal{H}$ which takes $\mathcal{M}'_{a_n} \bigoplus \mathcal{M}'_{b_n} = L^2(a_n,b_n)$ onto $E_n \mathcal{H}$. Then $\mathcal{M} = U\mathcal{M}'$ is a continuous nest, and $E_n$ is a partition of $\mathcal{M}$.

Since $C$ is uncountable, it supports a non-zero non-atomic measure $\nu$. Let $\mathcal{Q}$ be the continuous nest on $\mathcal{H} \bigoplus L^2(\nu)$ given by
\[ Q_t = M_t \oplus \{ f \in L^2(\nu) : \text{supp}(f) \subseteq [0,t] \} . \]

The map taking \( M_t \) to \( Q_t \) is an order isomorphism. By Theorem 13.10, there is an invertible operator \( S = U + K \) where \( U \) is unitary, \( K \) is compact and \( \| K \| < \epsilon/3 \) such that \( SM_t = Q_t \) for all \( t \) in \( \omega \). Since \( E_{\sharp} (C) = L^2(\mu) \), \( S \) does not preserve the partition \( \{ E_n \} \). Thus the same applies to \( U^* S = I + U^* K \). Let

\[ T = |I + U^* K| = ((I + U^* K)^* (I + U^* K))^{1/2} . \]

Since \( T = W(I + U^* K) \) where \( I + U^* K = W^* T \) is the polar decomposition, \( T \) also acts discontinuously. Clearly, \( T \) is positive and \( T - I \) is compact. Furthermore

\[ \| T^2 - I \| = \| K^* U + U^* K + K^* K \| < \epsilon . \]

So \( \| T - I \| < \epsilon \| T + I \|^{-1} < \epsilon . \) \( \square \)

Say that an interval \( E \) of \( \mathcal{N} \) has a non-atomic part if \( E \) is greater than the sum of the atoms it dominates. The interval \( E \) will be called countable or uncountable depending on the cardinality of the restriction \( \mathcal{N} |_{E \mathcal{N}} \). Lemma 13.18 will be used repeatedly to ensure that a nest similar to \( \mathcal{N} \) has a maximal non-atomic part.

**13.19 Lemma.** Let \( \mathcal{N} \) be a nest, and let \( \epsilon > 0 \) be given. There is a positive operator \( u \) such that \( T - I \) is compact and \( \| T - I \| < \epsilon \) such that \( T \mathcal{N} \) has non-atomic part on every uncountable interval.

**Proof.** Choose \( \epsilon_k > 0 \) such that \( \prod_{k=1}^{\infty} (1 + \epsilon_k) < 1 + \epsilon \). Fix a subset \( \omega \) of \([0,1]\)

order isomorphic to \( \mathcal{N} \), and let \( E_k \) be the spectral measure on \( \omega \). Positive operators \( S_n \) will be constructed so that \( S_n - I \) is compact and \( \| S_n - I \| < \epsilon_n \). Define \( T_n = S_n S_{n-1} \ldots S_1 \), and let \( \mathcal{N}_n = T_n \mathcal{N} \). If \( T_{n-1} \) has been defined, divide \( \omega \) into \( 2^n \) diadic intervals \( \{ k2^{-n}, (k+1)2^{-n} \} \). Let \( E_k \) be the corresponding intervals of \( \mathcal{N}_{n-1} \). If \( E_k \) is countable, or if \( E_k \) has a non-atomic part, define \( S_n | E_k = I | E_k \). If \( E_k \) is uncountable and atomic, use Lemma 13.18 define \( S_n | E_k = E_k S_n E_k \) so that \( E_k S_n E_k \) acts discontinuously on \( \mathcal{N}_{n-1} | E_k \). Thus \( S_n \mathcal{N}_{n-1} | E_k \mathcal{N} \) must have a non-atomic part.

Thus \( S_n = \sum_{k=1}^{n} S_n E_k \) is defined. The nest \( \mathcal{N}_n = T_n \mathcal{N} = S_n \mathcal{N}_{n-1} \) has the property that every diadic interval of length \( 2^{-n} \) is countable, or has non-atomic part.

Write \( S_n = I + K_n \). One readily verifies by induction that

\[ \| ((\prod_{j=1}^{n} I + K_j) - I) \| < \prod_{j=1}^{n} (1 + \epsilon_j) - \epsilon < \epsilon \]

and
\[ \| \prod_{j=1}^{m} (I + K_j) - \prod_{j=1}^{n} (I + K_j) \| < (1+\epsilon) (\prod_{j=n+1}^{\infty} (1+\epsilon_j))^{-1}. \]

So \( T = \lim_{t \to \infty} T_n \) converges on norm, and \( T-I \) is compact with \( \| T-I \| < \epsilon. \)

Let \( E \) be an interval of \( TN \). If \( E \) is uncountable, then \( E \) contains an uncountable diadic interval \( E_0 \) corresponding to \( (k2^{-n}, (k+1)2^{-n}) \). This interval has a non-atomic part in \( N_n \). Each operator \( S_k \) for \( k > n \) has been constructed so that it is the identity on the non-atomic part of \( N_{n-1} \). So \( E_0 \) still has a non-atomic part in the limit nest \( TN \).

Let \( P \) be the sum of all atoms of \( TN \). Then \( TN|\mathcal{P}^{\perp}H \) is a nonatomic (or continuous) nest. The support \( \omega_0 \) of this subnest intersects every uncountable interval. Since \( \omega_0 \) is closed, its complement consists of countably many open intervals, each of which must be countable. Indeed, \( \omega_0 \) is the set of points \( x \) in \( \omega \) such that every neighbourhood of \( x \) meets \( \omega \) in an uncountable set. Let \( \omega' \) denote the set of all limit points of \( \omega \). For each ordinal \( \alpha \), define \( \omega^{(\alpha)} = \omega^{(\beta)} \) if \( \alpha = \beta+1 \) and \( \omega^{(\alpha)} = \bigcup_{\beta < \alpha} \omega^{(\beta)} \) if \( \alpha \) is a limit ordinal. Then \( \omega_0 = \bigcap \omega^{(\alpha)} \) is the maximal perfect subset of \( \omega \).

13.20 Similarity Theorem. Let \( \mathcal{N} \) and \( \mathcal{M} \) be nests on a separable Hilbert space. Then \( \mathcal{N} \) and \( \mathcal{M} \) are similar if and only if there is a dimension preserving order isomorphism of \( \mathcal{N} \) onto \( \mathcal{M} \). Given \( \epsilon > 0 \) and any dimension preserving order isomorphism \( \theta \), there is an invertible operator \( S = U+K \) with \( U \) unitary, \( K \) compact, and \( \| K \| < \epsilon \) such that \( \mathcal{N} = \mathcal{M} \) and \( \theta S = \theta \).

Proof. Consider the non-trivial direction. Let \( \epsilon > 0 \) and \( \theta \) be given. Let \( \omega \) be a subset of [0,1] order isomorphic to \( \mathcal{N} \), and to \( \mathcal{M} \) also via \( \theta \). Using Lemma 13.19, one obtains operators \( X \) and \( Y \) such that \( X-I \) and \( Y-I \) are compact, and have norms at most \( \epsilon/4 \), and such that \( \mathcal{N'} = X \mathcal{N} \) and \( \mathcal{M'} = Y \mathcal{M} \) both have nonatomic parts with support \( \omega_0 \), the maximal perfect subset of \( \omega \). The map \( \theta' = \theta \gamma \theta^\mathcal{X} \) is an order preserving isomorphism of \( \mathcal{N'} \) onto \( \mathcal{M'} \). Let \( P \) and \( Q \) be the projections onto the atomic parts of \( \mathcal{N'} \) and \( \mathcal{M'} \). Since \( \theta' \) preserves dimension, there is a unitary operator \( U_0 \) from \( PH \) onto \( Q\mathcal{H} \) which carries each atom \( A \) of \( \mathcal{N} \) onto \( \theta'(A) \). The restriction of \( \theta' \) to \( \mathcal{N'}|\mathcal{P}^{\perp}H \) is an order isomorphism onto \( \mathcal{M'}|\mathcal{P}^{\perp}H \). By Theorem 13.10, there is an invertible operator \( S_0 = U_0 + K_0 \) where \( U_0 \) is unitary, \( K_0 \) is compact, and \( \| K_0 \| < \epsilon/4 \) such that \( S_0 \) takes \( \mathcal{N'}|\mathcal{P}^{\perp}H \) onto \( \mathcal{M'}|\mathcal{P}^{\perp}H \) and implements \( \theta' \). Let \( S' = U_0 \oplus S_0 = (U_0 \oplus U_0) + (0 \oplus K_0) \). It is clear that \( S' \) takes \( \mathcal{N'} \) onto \( \mathcal{M'} \) and implements \( \theta' \). Thus \( S = Y^{-1}S'X \) is the required similarity of \( \mathcal{N} \) onto \( \mathcal{M} \) with \( \theta S = \theta \). Clearly, \( S-I \) is compact of norm at most.
\[(1+\epsilon/4)^2(1-\epsilon/4)^{-1} - 1 < \epsilon\]

provided \(\epsilon < .05\). \(\blacksquare\)

**13.21 Corollary.** For two nests \(\mathcal{N}\) and \(\mathcal{M}\) on separable Hilbert spaces, the following are equivalent.

1) There is an order isomorphism of \(\mathcal{N}\) onto \(\mathcal{M}\) which preserves dimension.

2) \(\mathcal{N}\) and \(\mathcal{M}\) are similar.

3) \(\mathcal{N}\) and \(\mathcal{M}\) are approximately unitarily equivalent.

4) \(Q^T(\mathcal{N})\) and \(Q^T(\mathcal{M})\) are unitarily equivalent.

2') There is a unitary operator \(U\) and a compact operator \(K\) such that \((U+K)\mathcal{N} = \mathcal{M}\).

3') There is an approximate unitary equivalent \(\{U_n\}\) of \(\mathcal{N}\) onto \(\mathcal{M}\) such that \(U_n - U_0\) is compact for all \(n \geq 1\).

**Proof.** 1) implies 2') by Theorem 13.20. 2') easily implies 4). By Theorem 12.8, 4) implies 3') which in turn implies 3). Theorem 12.18 shows 3) implies 2) which readily implies 1). \(\blacksquare\)

**13.22 Example.** Consider the nests \(\mathcal{Q}\) and \(\mathcal{R}\) mentioned in section 13.15. The natural isomorphism \(\theta\) of \(\mathcal{Q}\) onto \(\mathcal{R}\) preserves dimension since all atoms are one dimensional. Thus, by Theorem 13.20, \(\mathcal{Q}\) and \(\mathcal{R}\) are similar. This is in spite of the fact that \(\mathcal{Q}\) is atomic and \(\mathcal{R}\) has a maximal continuous part. This is what Lemma 13.19 does to \(\mathcal{Q}\) in a much less precise way.

Recall from section 8.13 the ideal \(\mathcal{R}^\infty(\mathcal{N})\). It consists of those operators \(T\) in \(\mathcal{T}(\mathcal{N})\) such that for every \(\epsilon > 0\), there is a countable partition \(\mathcal{E}\) of \(\mathcal{N}\) such that \(\|\Delta_\mathcal{E}(T)\| < \epsilon\). It has a striking connection with absolute continuity.

**13.23 Theorem.** Let \(\mathcal{N}\) be a nest on a separable space, and let \(T\) be an invertible operator. The following are equivalent:

1) \(T\) acts absolutely continuously on \(\mathcal{N}\).

2) \(\mathcal{R}^\infty(\mathcal{TN})\) contains \(\mathcal{TR}^\infty(\mathcal{N})T^{-1}\).

3) \(\mathcal{R}^\infty(\mathcal{N})\) does not contain a non-zero indempotent \(P\) such that \(TPT^{-1}\) is self-adjoint.

**Proof.** 1) \(\Rightarrow\) 2). Let \(A\) belong to \(\mathcal{R}^\infty(\mathcal{N})\). Let \(\epsilon > 0\) be given, and let \(\mathcal{E}\) be a partition such that \(\|\Delta_\mathcal{E}(A)\| < \epsilon\). If \(T\) acts absolutely continuously, then by Lemma 13.16 the image \(\tilde{\mathcal{E}}\) is a partition of \(T\mathcal{N}\). Let \(E\) be an interval of \(\mathcal{E}\), and let \(\tilde{E}\) be the corresponding interval in \(T\mathcal{N}\). Write
\[ E = P(N_1) - P(N_0). \text{ Then } T^{-1} \hat{E} = P(N_1)T^{-1} \hat{E} \text{ and } \hat{ET} = \hat{ETP}(N_0)^\perp. \text{ So } \]
\[ \hat{ETAT}^{-1} \hat{E} = \hat{ETP}(N_0)^\perp AP(N_1)T^{-1} \hat{E} = \hat{ETEAT}^{-1} \hat{E}. \]

Thus \( \|\hat{ETAT}^{-1} \hat{E}\| \leq \|T\| \|T^{-1}\| \epsilon \), and hence \( TAT^{-1} \) belongs to \( \mathcal{R}^\infty(T\mathcal{N}) \).

2) \( \Rightarrow \) 3). By Proposition 8.13, \( \mathcal{R}^\infty(T\mathcal{N}) \cap D(T\mathcal{N}) = \{0\} \). So \( \mathcal{R}^\infty(T\mathcal{N}) \) contains no non-zero self-adjoint operator, and in particular cannot contain \( TPT^{-1} \) if this is a projection.

3) \( \Rightarrow \) 1). If \( T \) does not act absolutely continuously, then Lemma 13.16 provides a partition \( \mathcal{E} \) so that the corresponding intervals \( \hat{E} \) do not partition \( T\mathcal{N} \). Let \( Q = (\sum \hat{E} : \hat{E} \in \hat{\mathcal{E}})^\perp \) and let \( P = T^{-1}QT \). For each \( E = P(N_1) - P(N_0) \) in \( \mathcal{E} \),
\[ EPE = ET^{-1}P(TN_0)^\perp QT(TE) = ET^{-1}ETE = 0. \]

Thus \( P \) belongs to \( \mathcal{R}^\infty(\mathcal{N}) \) and \( TPT^{-1} = Q \) is self-adjoint.

**13.24 Corollary.** Let \( \mathcal{N} \) be a nest on a separable space. The following are equivalent:

1) \( \mathcal{N} \) is uncountable.

2) There is an invertible operator \( T \) which acts discontinuously on \( \mathcal{N} \).

3) \( \mathcal{R}^\infty(\mathcal{N}) \) contains a non-zero idempotent.

**Proof.** 1) implies 2) is Lemma 13.18. 2) implies 3) follows from Theorem 13.23. If \( P \) is a non-zero indempotent, then \( T = [PP^* + (I - P^*)(I-P)]^{\frac{1}{2}} \) is invertible and \( TPT^{-1} \) is self-adjoint. So 3) implies 2), again by Theorem 13.23. Finally, if \( \mathcal{N} \) is countable and \( T \) is invertible, then \( T\mathcal{N} \) is countable. So both nests are atomic and \( \theta_T \) implements a bijective correspondence between the atoms of \( \mathcal{N} \) and the atoms of \( T\mathcal{N} \). So the spectral measures are atomic with masses corresponding exactly, and thus \( T \) acts absolutely continuously on \( \mathcal{N} \). So 2) implies 1).

**Notes and Remarks.**

The main results of this chapter are due to Andersen, Larson, and Davidson. Theorem 13.9 is from Andersen [1]. The proof given here is due to Davidson [8]. A third proof was given by Arveson [10] generalizing his approach [9] to Voiulescu’s Theorem [2]. The proof of Lemma 13.7 was provided by G. Pedersen. Larson [4] proved that any two continuous nests are similar. The generalization, Theorem 13.10, is due to Davidson [6]. The examples and Corollary 13.14 are due to Larson. Larson [6] also proved Lemmas 13.16 and 13.18. The proofs given here are from Davidson [6], where Theorem 13.20 is proven. Larson’s Theorem solved an old problem due to Ringrose by showing that neither multiplicity nor measure class is preserved by similarity of nests. Andersen [2] showed that a weaker version follows immediately from his results and those of Lance [2]. Theorem 13.23 is also due to Larson.
Exercises.

13.1 Let $A$ and $B$ be self-adjoint operators on a separable Hilbert space. Theorem 7.15 shows that $A$ and $B$ are unitarily equivalent if and only if $\sigma(A) = \sigma(B)$ and they have the same measure class and multiplicity function.

(i) Show that if $A$ and $B$ are similar, then they are unitarily equivalent. Hint: If $AS = SB$ and $S = UP$ is the polar decomposition, then $(U^*AU)^k = P^kB$ for all $k \geq 1$.

(ii) Use the Weyl-von Neumann Theorem (Exercise 7.1) to show that $A$ and $B$ are approximately unitarily equivalent (i.e. there are a $U_n$ unitary such that $\|A - U_n^*BU_n\|$ tends to zero) if and only if $\sigma(A) = \sigma(B)$ and the multiplicities of isolated eigenvalues are equal.

(iii) Note the parallels and differences between the three equivalences (unitary, similarity, and approximate unitary) for self-adjoint operators and nests.

13.2 Prove the measure theoretic fact needed in Lemma 13.2.

Hint: Let $\nu_0, \nu_1, \ldots$ be mutually singular, non-atomic probability measures on $[0,1]$. Let $\nu = \sum_{n=0}^{\infty} 2^{-n} \nu_n$. Let $h_\mu(x) = \nu[0,x]$ and $h_\mu(x) = \mu[0,x]$. Let $E_k$ be disjoint Borel sets with union $[0,1]$ such that $\nu_n(E_k) = 1$. Define $F_k = h_\mu^{-1} o h_\nu(E_k)$. Let $A_n = F_n \cap J_n$ for $n \geq 1$ and $A_0 = J_0 \bigcup_{n=1}^{\infty} A_n$. Prove that $A_n$ satisfy the criterion.

13.3 (i) Let $\mathcal{G}$ be a finite group of operators under multiplication. Let $T = (\sum G G^*)^*$. Show that $T^* G = (G^{-1})^* T^*$ for all $G$ in $\mathcal{G}$. Hence deduce that $T^* T^{-1}$ is unitary for all $G$ in $\mathcal{G}$.

(ii) Let $\mathfrak{A}$ be a unital, norm closed algebra of operators. Suppose that $P$, $A$, $B$ belong to $\mathfrak{A}$ such that $I - P$, $A = PA(I - P)$, $B = (I - P)AP$, and $(A + B)^2 - I$ is compact. Show that there are $A' = PA(I - P)$ and $B' = (1 - P)BP$ in $\mathfrak{A}$ so that $A'A' = P$ and $B'B' = Q'$ are idempotent, and $P - P'$ and $I - P - Q'$ are finite rank.

(iii) Let $\mathfrak{A}$ be as in (ii). Suppose that $\mathfrak{A}/\mathfrak{A} \cap K$ contains elements $\alpha$, $\beta$ generating a group isomorphic to $S_3$ by satisfying $\alpha^2 = 1$, $\beta^3 = 1$, and $\alpha \beta = \beta^2 \alpha$. Use the Riesz functional calculus to obtain a preimage $B$ of $\beta$ in $\mathfrak{A}$ of the form $B = P_0 + \omega P_1 + \omega^2 P_2$ where $\omega = e^{2\pi i/3}$ and $P_0, P_1, P_2$ are commuting idempotents summing to $I$. Then obtain a preimage $A'$ of $\alpha$ in $\mathfrak{A}$ of the form $A' = P_0 A' P_0 + P_1 A' P_1 + P_2 A' P_1$. Use (ii) to modify $A'$ so that $P_1 A' P_2 A' P_1 = P_1$ and $P_2 A' P_1 A' P_2 = P_2$ are idempotents differing from $P_1$ and $P_2$ by a finite rank. Finally, adjust $A'$ to
A by another compact in $A \cap K$ so that $A^2 = I = B^3$ and $AB = B^2A$.

13.4 (Larson) Let $\mathcal{N}$ be the Volterra nest and let $\mathcal{M}$ be a continuous nest of uniform multiplicity 3. Then $\mathcal{M}$ contains a finite unitary group isomorphic to $S_3$. Use Andersen’s Theorem to obtain a copy of $S_3$ in $\mathcal{T}(\mathcal{N})/K$. Then using Exercise 13.3, obtain a copy of $S_3$ in $\mathcal{T}(\mathcal{N})$. Use Exercise 13.3 (i) to obtain a positive operator $T$ that unitarizes this group. Show that the nest $\mathcal{T}\mathcal{M}$ is not multiplicity free.

13.5 (Larson) If $\mathcal{M}$ is a continuous nest of multiplicity 2, then $\mathcal{M}'$ contains a partial isometry $U$ so that $UU^*-U^*U$ is invertible. Use Andersen’s Theorem to show that if $\mathcal{N}$ is any continuous nest, then $\mathcal{T}(\mathcal{N})/\mathcal{T}(\mathcal{N}) \cap K$ contains elements $\alpha$ and $\beta$ so that $\alpha\beta - \beta\alpha = 1$. Use the fact that $\mathcal{T}(\mathcal{N}) \cap K$ belongs to the radical to lift this to $\mathcal{T}(\mathcal{N})$. Conclude that the commutator ideal of $\mathcal{T}(\mathcal{N})$ (i.e. the ideal generated by all operators $AB-BA$) is all of $\mathcal{T}(\mathcal{N})$. Deduce this directly from the first sentence and theorem 13.10.

13.6 (Larson)

(a) Show that $R^\infty(\mathcal{N})$ is contained in the strong operator closure of the radical of $\mathcal{T}(\mathcal{N})$.

(b) If $\mathcal{N}$ and $\mathcal{M}$ are nests and $\mathcal{N}$ is contained in $\mathcal{M}$, show that $R^\infty(\mathcal{N})$ is contained in $R^\infty(\mathcal{M})$.

13.7* (i) Let $\mathcal{N}$ be the Volterra nest. Find an explicit operator $T$ so that $T\mathcal{N}$ is not multiplicity free.

(ii) Let $\mathcal{Q}$ be the Cantor nest. Find an explicit operator $T$ so that $T\mathcal{Q}$ is not purely atomic.

14. Factorization
15. Reflexivity, Ideals, and Bimodules
16. Duality
17. Isomorphisms
18. Perturbations of Operator Algebras
19. Derivations and Cohomology
20. Representations and Dilations of Nest Algebras
21. Operators in Nest Algebras
14. Factorization

In this chapter, we consider the following factorization questions and a number of variations.

Q1. Given a positive invertible operator $Q$ and a nest $\mathcal{N}$, when is there an invertible element $A$ of $\mathcal{T}(\mathcal{N})$ so that $Q = A^*A$?

Q2. Given an invertible operator $T$ in $\mathcal{T}(\mathcal{N})$, when can $T$ be factored as $T = UA$ where $U$ is a unitary in $\mathcal{T}(\mathcal{N})$ and $A$ is invertible in $\mathcal{T}(\mathcal{N})$?

14.1 Lemma. Let $T$ be an invertible operator, and let $\mathcal{N}$ be a nest. The following are equivalent:
1) there is an $A$ in $\mathcal{T}(\mathcal{N})^{-1}$ such that $A^*A = TT$,
2) there is an $A$ in $\mathcal{T}(\mathcal{N})^{-1}$ and a unitary operator $U$ such that $T = UA$,
3) there is a unitary operator $U$ so that $TN = UN$ for all $N$ in $\mathcal{N}$,
4) $T$ preserves the multiplicity and measure class of $\mathcal{N}$.

Proof. Suppose 1) holds. Then $|T| = |A|$ and hence by the polar decompositions $T = V|T|$ and $A = W|T|$, one has $T = UA$ where $U = VW^-$. Given 2), one has $AN$ contained in $N$ and $A^{-1}N$ contained in $N$, whence $AN = N$ for all $N$ in $\mathcal{N}$. Hence $TN = U(AN) = UN$ for all $N$ in $\mathcal{N}$. Given 3), $A = UT$ carries $N$ onto $N$ for every $N$ in $\mathcal{N}$. Hence $A$ and $A^{-1}$ belong to $\mathcal{T}(\mathcal{N})$. Clearly $A^*A = TT$ so 1) holds. The equivalence of 3) and 4) is Corollary 7.16.

14.2 Theorem. Let $\mathcal{N}$ be a nest on a separable Hilbert space.

1) If $\mathcal{N}$ is countable, then every positive invertible operator $Q$ factors as $Q = A^*A$ for some $A$ in $\mathcal{T}(\mathcal{N})^{-1}$.

2) If $\mathcal{N}$ is countable and $\epsilon > 0$, then there is a positive operator $Q = I + K$ where $K$ is compact and $\|K\| < \epsilon$ such that $Q$ does not factor as $A^*A$ for any $A$ in $\mathcal{T}(\mathcal{N})^{-1}$.

Proof. Let $\mathcal{N}$ be countable, and consider the nest $Q^{\mathcal{N}} \mathcal{N}$ and the order isomorphism $\theta = \theta_{\mathcal{Q}^{\mathcal{N}}}$. Countable nests are atomic, and $\theta$ preserves dimension. So $\theta$ preserves multiplicity and measure class. By Lemma 14.1, $Q$ has the desired factorization.

If $\mathcal{N}$ is uncountable, then by Lemma 13.18, there is a positive operator $T = I + K$ with $K$ compact and $\|K\| < \epsilon/3$ so that $T$ fails to act
absolutely continuously on $\mathcal{H}$. By Lemma 14.1, $Q = T^*T$ fails to have the
desired factorization. 

14.3 Corollary. Let $\mathcal{H}$ be a countable nest and suppose that $T$ is an
invertible operator in $\mathcal{T}(\mathcal{H})$. Then $T$ factors as $T = UA$ where $U$ is a
unitary in $\mathcal{T}(\mathcal{H})$ and $A$ belongs to $\mathcal{T}(\mathcal{H})^{-1}$.

Proof. By Theorem 14.2, there is an $A$ in $\mathcal{T}(\mathcal{H})^{-1}$ such that $T^*T = A^*A$.
Let $U = TA^{-1}$. Then for each $N$ in $\mathcal{H}$,

$$UN = T(A^{-1}N) = TN \subseteq N.$$ 

So $U$ is a unitary in $\mathcal{T}(\mathcal{H})$ as desired. 

However, one can always get a "weak factorization".

14.4 Lemma. Let $\mathcal{H}$ be a nest on a separable space $\mathcal{H}$, and let $T$ be an
invertible operator in $\mathcal{B}(\mathcal{H})$. Then $T$ factors as $T = US$ where $U$ is unitary
and $S$ belongs to $\mathcal{T}(\mathcal{H})$.

Note: $S$ is invertible, but in general, $S^{-1}$ does not belong to $\mathcal{T}(\mathcal{H})$.

Proof. The countable case follows from Theorem 14.2 and the
equivalence of 1) and 2) in Lemma 14.1. Assume that $\mathcal{H}$ is uncountable, and define

$$N_{-\infty} = \bigvee\{N \in \mathcal{H}: N \land N \text{ is countable}\}$$

$$N_{+\infty} = \bigwedge\{N \in \mathcal{H}: N \lor N \text{ is countable}\}.$$ 

The $\{N \in \mathcal{H}: N \leq N_{-\infty}\}$ and $\{N \in \mathcal{H}: N \geq N_{+\infty}\}$ are countable and the
intervals $[N_{-\infty}, N]$ and $[N, N_{+\infty}]$ are uncountable whenever
$N_{-\infty} < N < N_{+\infty}$. Hence one may choose a sequence $N_n$ in $\mathcal{H}$, $n \in \mathbb{Z}$
such that $N_n < N_{n+1}$ and $N_{n+1} \ominus N_n$ is infinite dimensional for all $n$ in
$\mathbb{Z}$, and $\bigwedge N_n = N_{-\infty}$ and $\bigvee N_n = N_{+\infty}$. Let $\mathcal{H}_0$ be the countable nest
given by $\{N \in \mathcal{H}: N \leq N_{-\infty}\} \cup \{N_n, n \in \mathbb{Z}\} \cup \{N \in \mathcal{H}: N \geq N_{+\infty}\}$.

Let $T$ be a given invertible operator. By the countable case, there is
a unitary $W$ such that $W^*T$ belongs to $\mathcal{T}(\mathcal{H}_0)^{-1}$. Let $V$ be a unitary operator
which is the identity on $N_{-\infty} \oplus N_{+\infty}$ and carries $N_{n+1} \ominus N_n$ onto
$N_n \ominus N_{n-1}$ for all $n$ in $\mathbb{Z}$. Then $A = W^*T$ takes $N_{n+1}$ into $N_n$ for
every $N$ in $\mathbb{Z}$. It also takes $N$ onto itself if $N \leq N_{-\infty}$ or $N \geq N_{+\infty}$. So
$A$ belongs to $\mathcal{T}(\mathcal{H})$. Thus $T = (WV^*)A$ is the desired factorization. 

The corresponding version for positive operators is immediate, and leads to a complement of Corollary 14.3.

14.5 Corollary. Let \( N \) be a nest on a separable space. For every positive invertible operator \( Q \), there is an operator \( T \) in \( \mathbb{T}(N) \) so that \( Q = TT^* \).

**Proof.** By Lemma 14.4, factor \( Q^{1/2} = UT \) where \( T \) belongs to \( \mathbb{T}(N) \) and \( U \) is unitary. \( \blacksquare \)

14.6 Corollary. Let \( N \) be an uncountable nest on a separable Hilbert space. Then there is an invertible operator \( T \) in \( \mathbb{T}(N) \) which does not factor as \( T = UA \) for any \( A \) in \( \mathbb{T}(N)^{-1} \) and \( U \) unitary.

**Proof.** Let \( Q \) be a positive, invertible operator provided by Theorem 14.2 which does not factor as \( A^*A \) for any \( A \) in \( \mathbb{T}(N)^{-1} \). Let \( T \) be an operator in \( \mathbb{T}(N) \) such that \( T^*T = Q \) as provided by Corollary 14.5. The equivalence of 1) and 2) of Lemma 14.1 shows that \( T \) fails to have the desired factorization. \( \blacksquare \)

Now we consider the class of invertible, positive operators of the form \( I+A \) where \( A \) belongs to the Macaev ideal \( C_w \). It will be shown that these operators have a good factorization with respect to any nest. The key is the boundedness of triangular truncation.

14.7 Lemma. Let \( N \) be a nest, and let \( A \) belong to \( C_w \) with \( \|A\|_w < 1 \). Then \( I+A \) has a unique factorization of the form

\[
I+A = (I+K_{+})(I+D)(I+K_{+})
\]

where \( K_{+} \) belongs to \( K \cap \operatorname{rad} \mathbb{T}(N) \), \( K_{-} \) belongs to \( K \cap \operatorname{rad} \mathbb{T}(K_{+}) \), and \( D \) belongs to \( K \cap D(N) \). If \( A \) is self-adjoint, then \( K_{+} = K_{+}^* \) and \( D = D^* \).

**Proof.** First we prove uniqueness without any condition on \( \|A\|_w \). Suppose \( (I+L_{-})(I+E)(I+L_{+}) \) is another factorization. Then \( (I+L_{-})^{-1}-I = \sum_{n \geq 1} L_{-}^{n} \) belongs to \( \operatorname{rad} \mathbb{T}(N) \) and \( (I+K_{+})^{-1}-I \) belongs to \( \operatorname{rad} \mathbb{T}(N) \). Hence

\[
(I+L_{-})^{-1}(I+K_{-}) = (I+E)(I+L_{+})(I+K_{+})^{-1}(I+D)^{-1}.
\]

The left hand side belongs to \( I+\operatorname{rad} \mathbb{T}(N) \) whereas the right hand side belongs to \( \mathbb{T}(N) \). Hence both are equal to \( I \). So \( L_{-} = K_{-} \), and likewise
\(L_+ = K_+.\) Hence \(E = D\) and uniqueness is obtained. If \(A = A^*\), then

\[I + A = (I + K_+^*)(I + D^*)(I + K_-^*)\]

and uniqueness implies that \(K_- = K_+^*\) and \(D = D^*\).

So consider existence. It is enough to obtain a factorization \(I + A = (I + B_-)(I + B_+)\) where \(B_-\) belongs to \(K \cap \text{rad} \, T(\mathcal{N}^\perp)\) and \(B_+\) belongs to \(K \cap T(\mathcal{N})\). Then if \(D = \Delta(B_+),\) one sets \(I + K_+ = (I + D)^{-1}(I + B_+).\) Since \(\Delta\) is a homomorphism on \(T(\mathcal{N}),\) one obtains \(\Delta(K_+) = 0\) and hence by Corollary 6.8, \(K_+\) belongs to \(K \cap \text{rad} \, T(\mathcal{N})\). Recall Theorem 4.16 which shows that the triangular projection \(P = \mathcal{U}_\mathcal{N}\) maps \(C_\mathcal{N}\) onto \(K \cap T(\mathcal{N})\) and has norm one. Likewise, \(P^\perp = I - P = \mathcal{L}_{\mathcal{N}^\perp}\) maps \(C_\mathcal{N}\) into \(K \cap \text{rad} \, T(\mathcal{N}^\perp)\) and has norm one.

Suppose that the factorization \(I + A = (I + B_-)(I + B_+)\) exists and define \(C_\pm\) by \(I + C_+ = (I + B_+)^{-1}\) and \(I + C_- = (I + B_-)^{-1}\) and note that \(C_+\) belongs to \(K \cap T(\mathcal{N})\) and \(C_-\) belongs to \(K \cap \text{rad} \, T(\mathcal{N}^\perp).\) One obtains

\[I + B_+ = (I + C_-)(I + A) = I + C_+ A + C_- A .\]

Cancelling and applying \(P^\perp\) to both sides yields

\[0 = C_- + P^\perp A + P^\perp(C_- A) .\]

Let \(R_\mathcal{N}\) denote the operator taking \(\mathcal{B}(\mathcal{N})\) into \(C_\mathcal{N}\) by \(R_\mathcal{N}(X) = XA.\) This has norm \(\|R_\mathcal{N}\| = \|A\|_w < 1.\) One obtains

\[(I + P^\perp R_\mathcal{N})(C_-) = -P^\perp(A) .\]

Since \(P^\perp R_\mathcal{N}\) maps \(\mathcal{B}(\mathcal{N})\) into itself (in fact into \(K \cap \text{rad} \, T(\mathcal{N}^\perp)\)) and \(\|P^\perp R_\mathcal{N}\| \leq \|A\| < 1,\) \(I + P^\perp R_\mathcal{N}\) is invertible. Hence

\[C_- = -(I + P^\perp R_\mathcal{N})^{-1}P^\perp(A) .\]

Similarly, if \(L_\mathcal{N}(X) = AX\) is left multiplication, one obtains

\[C_+ = -(I + P^\perp L_\mathcal{N})^{-1}P(A) .\]

So, given \(A,\) define \(C_+\) and \(C_-\) by these formulae and let \(B_+ = R(A + C_- A)\) and \(B_- = P^\perp(A + AC_+).\) Now,

\[(I + C_-)(I + A) = I + C_- A + C_- A\]

\[= I + (C_- + P^\perp(A) + P^\perp(C_- A)) + P(A + C_- A)\]

\[= I + P(A + C_- A) = I + B_+ ,\]

and \(B_+\) belongs to \(K \cap T(\mathcal{N}).\) Likewise, one obtains

\[(I + A)(I + C_+) = I + P^\perp(A + AC_+) = I + B_-\]

and \(B_-\) belongs to \(K \cap \text{rad} \, T(\mathcal{N}^\perp).\) So
\[(I+C_-)(I+B_-) = (I+C_-)(I+A)(I+C_+) = (I+B_-)(I+C_+) \cdot \]

This product belongs to \(\{I+\text{rad } \mathcal{T}(\mathcal{N}^\perp)\} \cap \{I+K \cap \mathcal{T}(\mathcal{N})\} = \{I\}.\) Thus, \(I+B_- = (I+C_-)^{-1}\) and \(I+B_+ = (I+C_+)^{-1}\). (These operators are Fredholm of index zero, so one sided inverses imply invertibility.) Hence

\[(I+B_-)(I+B_+) = (I+B_-)(I+C_-)(I+A)(I+C_+)(I+B_+) = I+A.\]

### 14.8 Lemma

Let \(\mathcal{N}\) be a nest, and let \(F\) be a finite rank operator such that \(I+F\) is positive and invertible. Then \(I+F\) factors as \((I+K)^*(I+D)(I+K)\) where \(K\) belongs to \(K \cap \text{rad } \mathcal{T}(\mathcal{N})\) and \(D\) belongs to \(K \cap \mathcal{D}(\mathcal{N})\).

**Proof.** This will be proven by induction on \(k = \text{rank } F\). Consider \(k = 1\). If \(\text{rank } F = 1\) and \(\|F\| < 1\), then \(\|F\|_\infty = \|F\|\) so the previous lemma provides the desired factorization. If \(\|F\| \geq 1\), then \(F\) must be positive of the form \(\alpha x \otimes x^*\) where \(\|x\| = 1\) and \(\alpha \geq 1\). So \((I+F)^{-1} = I - \frac{\alpha}{1-\alpha} x \otimes x^*.\) Since \(|\alpha(1-\alpha)^{-1}| < 1\), apply Lemma 14.7 to \((I+F)^{-1}\) and \(\mathcal{N}^\perp\). So

\[(I+F)^{-1} = (I+L^*)(I+E)(I+L)\]

where \(E\) belongs to \(\mathcal{D}(\mathcal{N})\) and \(L\) belongs to \(K \cap \text{rad } \mathcal{T}(\mathcal{N}^\perp).\) Thus

\[I+F = (I+L)^{-1}(I+E)^{-1}(I-L^*)^{-1} = (I+K^*)(I+D)(I+K)\]

where \(K = (I+L^*)^{-1} - I\) belongs to \(K \cap \text{rad } \mathcal{T}(\mathcal{N}^\perp)^* = K \cap \text{rad } \mathcal{T}(\mathcal{N})\), and \(D = (I+E)^{-1} - I\) belongs to \(\mathcal{D}(\mathcal{N})\) and \(K\).

Now suppose that the lemma holds for all eligible \(F\) of rank less than \(k\), for \(k \geq 2\). For \(F\) of rank \(k\), write \(F = F_1 + F_2\) where \(F_1\) is rank one and \(F_2\) has rank \(k-1\). Then \(I+F_1\) is positive and invertible, so factors as \((I+K_1^*)(I+D_1)(I+K_1) = (I+L^*)(I+L)\) where \(I+L = (I+D_1)^\mathcal{N}(I+K_1)\) and \(L\) belongs to \(\mathcal{T}(\mathcal{N}) \cap K\). Then

\[(I+L^*)(I+F)(I+L)^{-1} = I+(I+L^*)^{-1}F_2(I+L)^{-1} = I+G.\]

Furthermore, \(\text{rank } G = k-1\). So \(I+G\) factors as \((I+M^*)(I+M)\) for some \(M\) in \(K \cap \mathcal{T}(\mathcal{N})\). Hence

\[I+F = (I+L^*)(I+M^*)(I+M)(I+L) = (I+S^*)(I+S)\]

where \(S = L+M+ML\) belongs to \(\mathcal{T}(\mathcal{N}) \cap K\). Let

\[I+D = (I+\Delta(S^*))(I+\Delta(S))\]

and
\[ I+K = (I+\Delta(S))^{-1}(I+S) . \]

Then \( I+F = (I+K^*)(I+D)(I+K) \). Clearly, \( D \) belongs to \( \mathcal{D}(\mathcal{H}) \cap \mathcal{K} \), and \( K \) belongs to \( \mathcal{K} \cap \mathcal{T}(\mathcal{H}) \) and satisfies \( \Delta(K) = 0 \). By Corollary 6.8, \( K \) belongs to \( \text{rad} \mathcal{T}(\mathcal{H}) \).

**14.9 Theorem.** Let \( \mathcal{H} \) be any nest, and let \( A \) belong to \( \mathcal{C}_w \) be such that \( I+A \) is positive and invertible. Then \( I+A \) factors uniquely as

\[ I+A = (I+K^*)(I+D)(I+K) = (I+C)^*(I+C) \]

where \( D \) belongs to \( \mathcal{D}(\mathcal{H}) \cap \mathcal{K} \) and \( K \) belongs to \( \mathcal{K} \cap \text{rad} \mathcal{T}(\mathcal{H}) \), and \( C \) belongs to \( \mathcal{K} \cap \mathcal{T}(\mathcal{H}) \).

**Proof.** Let \( E \) be a finite rank spectral projection of \( A \) such that \( \|E^{1/2}A\| < 1 \). By Lemma 14.7, \( I+E^{1/2}A \) factors as \( (I+C^*_1)(I+C_1) \) for \( C_1 \) in \( \mathcal{K} \cap \mathcal{T}(\mathcal{H}) \). So

\[ (I+C^*_1)(I+D)(I+C_1)^{-1} = I+(I+C^*_1)EA(I+C_1) = I+F . \]

This operator satisfies the hypotheses of Lemma 14.8 and hence factors as \( (I+C^*_2)(I+C_2) \). Thus

\[ I+A = (I+C^*_1)(I+C^*_2)(I+C_2)(I+C_1) = (I+C)^*(I+C) \]

where \( C = C_1+C_2+C_2C_1 \). As in the previous lemma, one can factor out the diagonal part to obtain \( I+A = (I+K^*)(I+D)(I+K) \). The uniqueness follows as in Lemma 14.7.

**14.10 Corollary.** Let \( \mathcal{H} \) be a nest and let \( A \) belong to \( \mathcal{C}_w \) and let \( U \) be a unitary operator such that \( U+A \) is invertible. Then the order isomorphism \( \theta_{U+A} \) of \( \mathcal{H} \) onto \( (U+A)\mathcal{H} \) is implemented by a unitary operator.

**Proof.** By Lemma 14.1, this reduces to showing that \( (U+A)^*(U+A) = I+B \) factors as \( T^*T \) for some \( T \) in \( \mathcal{T}(\mathcal{H})^{-1} \). But \( I+B \) is positive and invertible, and \( B \) belongs to \( \mathcal{C}_w \). So this is a consequence of Theorem 14.9.

**14.11.** Next, we wish to consider factorizations of operators which are not invertible. A replacement is needed for the elements of \( \mathcal{T}(\mathcal{H})^{-1} \). As these operators are characterized as those operators \( A \) such that \( AN = N \) for all \( N \) in \( \mathcal{H} \), the following definition is an appropriate generalization. An operator \( A \) in \( \mathcal{T}(\mathcal{H}) \) is called outer if the range projection \( P(R_A) \) commutes with \( \mathcal{H} \) and \( AN \) is dense in \( N \cap R_A \) for every \( N \) in \( \mathcal{H} \). A partial isometry \( U \) in \( \mathcal{T}(\mathcal{H}) \) is called inner if \( U^*U \) commutes with \( \mathcal{H} \). One can now ask if a positive operator \( P \) factors as \( A^*A \) for \( A \) outer, and if every \( T \)
in $\mathcal{T}(\mathcal{H})$ factors as $T = UA$ with $A$ outer and $U$ inner. These definitions parallel well known factorizations of $L^\infty$ functions with respect to the subalgebra $H^\infty$ on the unit circle. This connection is made explicit in Exercise 14.12.

Recall that a set is well ordered if every subset has a least element. Such sets are order isomorphic to some ordinal, and are characterized by the fact that every element has an immediate successor. So $\mathcal{N}$ is well ordered if and only if $N \neq N_+$ for every $N$ in $\mathcal{N}$ (except $N = \emptyset$).

14.12 Proposition. Let $\mathcal{N}$ be a nest which is not well ordered. Then there is a positive operator $Q$ which cannot be factored as $A^*A$ for any outer operator $A$ in $\mathcal{T}(\mathcal{H})$.

Proof. Pick $N_0$ in $\mathcal{N}$ such that $N_0 = (N_0)_+$. Let $x$ be a unit vector in $N_0^\perp$ which is not in $N_0^\perp$ for any $N > N_0$. Set $Q = x \otimes x^*$. Suppose $Q = A^*A$ and $A$ is in $\mathcal{T}(\mathcal{N})$. Then $A$ is rank one, so $A = y \otimes z^*$ for some $y$ in $\mathcal{H}$. By Lemma 3.7, $y$ must belong to $N_0$. Then $y$ belongs to $R_A$ so $AN_0 = \{0\}$ is not dense in $R_A \cap N_0$. Thus $A$ is not outer. \Box

We wish to prove that such factorizations always exist in the well ordered case. This takes some preparation.

14.13 Lemma. Let $\begin{bmatrix} A & B \\ B^* & D \end{bmatrix}$ represent a positive operator on $\mathcal{H}_1 \oplus \mathcal{H}_2$. Then there is a bounded operator $X$ so that $B = A^*X$ and $RX$ is contained in $R_A$. On the other hand, if $B$ has this form, then $\begin{bmatrix} A & B \\ B^* & D \end{bmatrix}$ is positive if and only if $D \geq X^*X$.

Proof. Let $\delta \geq \|D\|$. Since

$$0 \leq \begin{bmatrix} A & B \\ B^* & D \end{bmatrix} \leq \begin{bmatrix} A & B \\ B^* & \delta I \end{bmatrix}$$

one has

$$0 \leq \begin{bmatrix} \delta I & -B \\ B^* & \delta I \end{bmatrix} \begin{bmatrix} A & B \\ B^* & \delta I \end{bmatrix} = \delta (\delta A - BB^*) .$$

For $\delta > 0$, one obtains $BB^* \leq \delta A$. So if $D = 0$, then $B = 0$. Otherwise, one has $\|B^*\| \leq \delta^k A^k$. So there is an operator $X$ in $\mathcal{B}(\mathcal{H}_2, \mathcal{H}_1)$ with $\|X\| \leq \delta^k$ so that $B^* = X^*A^k$ and $B = A^kX$. This $X$ is unique provided that it is stipulated that $X^*$ is zero on $R_A^\perp$. Thus $RX$ is contained in $R_A$. 

Now suppose that \( B = A^kX \) and \[
\begin{bmatrix}
A & B \\
B^* & D
\end{bmatrix}
\geq 0.
\] For \( t > 0 \), let \( E_t \) denote the spectral projection \( E_A[t,\infty) \). From the normal functional calculus, there is a positive operator \( T_t \) in \( W(A) \) such that \( T_t A^k = A^k T_t = E_t \). So
\[
0 \leq \begin{bmatrix} X^*T_t & I \end{bmatrix} \begin{bmatrix} A & A^kX \\
X^*A^k & D \end{bmatrix} \begin{bmatrix} -T_tX \\
I \end{bmatrix} = D - X^*E_tX.
\]
So \( X^*E_tX \leq D \). Letting \( t \) tend to zero yields \( X^*X \leq D \) since \( R_X \) is contained in \( R_A \). Conversely, if \( D \geq X^*X \),
\[
\begin{bmatrix} A & B \\
B^* & D \end{bmatrix} = \begin{bmatrix} A & A^kX \\
X^*A^k & X^*X \end{bmatrix} + \begin{bmatrix} 0 & 0 \\
0 & D - X^*X \end{bmatrix} = \begin{bmatrix} A^k & 0 \\
0 & X^* \end{bmatrix} \begin{bmatrix} A^k & X \\
0 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\
0 & D - X^*X \end{bmatrix} \geq 0.
\]

14.14 Corollary. If \( Q = \begin{bmatrix} A & B \\
B^* & D \end{bmatrix} \) is positive, then there is an upper triangular operator \( T = \begin{bmatrix} A^k & X \\
0 & (D - X^*X)^{1/2} \end{bmatrix} \) with the properties that (i) \( Q = TT^* \) and (ii) for any operator \( U \), \( UQ \) is upper triangular if and only if \( UT^* \) is upper triangular.

Proof. That \( TT^* = Q \) is immediate from the previous proof. Write \( U = [U_{ij}]_{1 \leq i,j \leq 2} \). Then \( UT^* \) is upper triangular exactly when \( U_{21}A^k + U_{22}X^* = 0 \). Also \( UQ \) is upper triangular exactly when
\[
0 = U_{21}A + U_{22}B^* = (U_{21}A^k + U_{22}X^*)A^k.
\]
Since \( X^* \) is zero on \( R_A \), these two conditions are equivalent. ■

14.15. When \( D = X^*X \), \( T^* = \begin{bmatrix} A^k & 0 \\
X^* & 0 \end{bmatrix} \). So if \( UT^* \) is upper triangular, it has the form \( \begin{bmatrix} * & 0 \\
0 & 0 \end{bmatrix} \). Thus, the 2-2 entry of \( UQ \) is \( (U_{21}A^k + U_{22}X^*)X = 0 \).

So \( UQ \) has the form \( \begin{bmatrix} * & * \\
0 & 0 \end{bmatrix} \). The separate matrix entries of \( Q \) belong to the \( C^* \)-algebra generated by \( Q \) and \( C^*(\mathcal{N}) \). So as in the proof of the polar decomposition, one obtains that \( X \) belongs to the von Neumann algebra generated by \( Q \) and the nest. Hence \( T \) belongs to this von Neumann
Let \( \mathcal{N} \) be a nest and let \( Q \) be a positive operator. For each element \( N \) of \( \mathcal{N} \), decompose \( Q \) on \( N \oplus N^\perp \) as \[
\begin{pmatrix}
A & B \\
B^* & X^n \end{pmatrix}
\]
Let \( X \) be the operator provided by Lemma 14.9 so that \[
\begin{pmatrix}
A & B \\
B^* & X^n \end{pmatrix}
\]
is the minimal positive operator with entries \( \begin{pmatrix} A & B \\ B^* & * \end{pmatrix} \). Define \( Q[0,N] \) to be this operator. If \( N \) and \( M \) belong to \( \mathcal{N} \) with \( N < M \), set
\[
Q[N,M] = Q[0,M] - Q[0,N].
\]
With respect to the decomposition \( N \oplus (M \ominus N) \oplus M^\perp \), \( Q[N,M] \) has the form
\[
\begin{pmatrix}
0 & 0 & 0 \\
0 & A & B \\
0 & B^* & X
\end{pmatrix}.
\]

**14.16 Lemma.** \[
\begin{pmatrix}
A & B \\
B^* & D
\end{pmatrix}
is positive if and only if \( D \geq X \).
\]

**Proof.** First write \( Q \) with respect to the given decomposition as \( [Q_{ij}]_{1 \leq i,j \leq 3} \). Then
\[
Q[0, M] = \begin{pmatrix}
Q_{11} & Q_{12} & Q_{13} \\
Q_{21} & Q_{22} & Q_{23} \\
Q_{31} & Q_{32} & Y
\end{pmatrix}
\text{ and } Q[0, N] = \begin{pmatrix}
Q_{11} & Q_{12} & Q_{13} \\
Q_{21} & D_{22} & D_{23} \\
Q_{31} & D_{32} & D_{33}
\end{pmatrix}.
\]
Furthermore \( [D_{ij}]_{1 \leq i,j \leq 3} \) and \( Y \) are the minimal operators making \( Q[0, M] \) and \( Q[0, N] \) positive. In particular, it follows that
\[
\begin{pmatrix}
Q_{22} & Q_{23} \\
Q_{32} & Y
\end{pmatrix} \geq \begin{pmatrix}
D_{22} & D_{23} \\
D_{32} & D_{33}
\end{pmatrix}
\]
and hence \( Q[0, M] \geq Q[0, N] \). Thus \( Q[N, M] \) is positive. A fortiori, if \( D \geq X \), then
\[
\begin{pmatrix}
A & B \\
B^* & D
\end{pmatrix} \geq \begin{pmatrix}
A & B \\
B^* & X
\end{pmatrix} = \begin{pmatrix}
Q_{22} & Q_{23} \\
Q_{32} & Y
\end{pmatrix} - \begin{pmatrix}
D_{22} & D_{23} \\
D_{32} & D_{33}
\end{pmatrix} \geq 0.
\]

On the other hand, if \( D \) is such that this matrix is positive, then
\[
0 \leq Q[0,N]^+ = \begin{bmatrix} Q_{11} & Q_{12} & Q_{13} \\
Q_{21} & Q_{22} & Q_{23} \\
Q_{31} & Q_{32} & D_{33}^+D 
\end{bmatrix}.
\]

The minimality of \( Y \) yields \( D_{33}^+D \geq Y \) or \( D \geq Y - D_{33} = X \).

**14.17 Lemma.** If \( N = N_\alpha \), then \( Q[0,N] = \lim_{M \uparrow N} Q[0,M] \).

**Proof.** With respect to \( N \uplus N^\perp \), \( Q[0,N] \) has the form \( \begin{bmatrix} A & B \\
B^* & D \end{bmatrix} \). And with respect to \( M \uplus M^\perp \), \( Q[0,M] \) has the form \( \begin{bmatrix} P(M)A P(M) & P(M)B \\
B^*P(M) & D \end{bmatrix} \).

The net \( Q[0,M] \) is an increasing net of positive operators bounded above by \( Q[0,N] \). Hence it converges in the strong operator topology to a limit \( Q' \). From the matrix form, it is clear that \( Q' \) has a decomposition with respect to \( N \uplus N^\perp \) as \( \begin{bmatrix} A & B \\
B^* & D' \end{bmatrix} \). As \( 0 \leq Q' \leq Q[0,N] \), then minimality of \( D \) yields \( Q' = Q[0,N] \).

**14.18 Lemma.** Let \( \mathcal{N} \) be a well ordered nest, and let \( Q \) be a positive operator. For each \( N \) in \( \mathcal{N} \) (except \( N_0 \)), let \( Q_N = Q[N,N_+]. \) For each finite subnest \( \mathcal{J} = \{F_0 < F_1 < ... < F_n = N\} \), set \( Q_\mathcal{J} = \sum_{j=0}^{n-1} Q_{F_j} \). Then \( Q_\mathcal{J} \) converges to \( Q \) in the strong operator topology.

**Proof.** Let the order type of \( \mathcal{N} \) be \( \alpha+1 \), and write \( \mathcal{N} = \{N_{\beta} : \beta \leq \alpha \} \). Consider the set \( S \) of ordinals \( \gamma \) such that \( s - \lim_{\mathcal{J} \subseteq \mathcal{N}_\gamma} Q_\mathcal{J} = Q[0,N_\gamma] \) where \( \mathcal{N}_\gamma = \{N_\beta : \beta \leq \gamma \} \). This set clearly contains all finite \( \gamma \). Furthermore, if \( S \) contains \( \gamma_0 \), then since \( Q[0,N_{\gamma_0+1}] = Q[0,N_{\gamma_0}] + Q[0,N_{\gamma_0+1}] \), then \( S \) contains \( \gamma_0+1 \). Suppose \( \gamma \) is a limit ordinal, \( \gamma = \lim_{\mathcal{J} \subseteq \mathcal{N}_\gamma} \gamma_n \) and \( \gamma_n \) belong to \( S \). Then for every \( \mathcal{J} \subseteq \mathcal{N}_\gamma \), one has (setting \( \gamma_0 = N_\gamma \))

\[
Q_\mathcal{J} = \sum_{j=1}^{n-1} Q[F_j,F_{j+1}] \leq \sum_{j=0}^{n-1} Q[F_j,F_{j+1}] = Q[0,N_{\gamma_n}].
\]

On the other hand

\[
s - \lim_{\mathcal{J} \subseteq \mathcal{N}_\gamma} Q_\mathcal{J} \geq s - \lim_{n \to \infty} (s - \lim_{\mathcal{J} \subseteq \mathcal{N}_{\gamma_n}} Q_\mathcal{J}) = Q[0,N_{\gamma_n}] = Q[0,N_{\gamma_n}]
\]

by Lemma 14.17. So equality holds and \( \gamma \) belongs to \( S \). By transfinite induction, \( \alpha \) belongs to \( S \). So \( s - \lim Q_\mathcal{J} = Q \).

\[\Box\]
14.19 Theorem. Let $\mathcal{N}$ be a well ordered nest. Then every positive operator $Q$ factors as $A^*A$ for some outer operator $A$ in $\mathcal{T}(\mathcal{N})$. Furthermore, $A$ can be chosen in $\{Q, \mathcal{M}\}''$ so that for every operator $U$, $UQ$ belongs to $\mathcal{T}(\mathcal{N})$ precisely when $UA^*$ does.

Proof. For each $N$ in $\mathcal{N}$, let $Q_N = Q[N_+,N_+]$ and let $E_N$ be the orthogonal projection onto $N_+ \ominus N$. By Lemma 14.16 and Corollary 14.14, the positive operator $Q_N$ factors as $A_N^*A_N$ where $A_N$ has the form

$$A_N = \begin{bmatrix} 0 & 0 & 0 \\ 0 & A & X \\ 0 & 0 & 0 \end{bmatrix}$$

with respect to the decomposition $N \oplus E_N \mathcal{H} \oplus N_+^\perp$. Since $A_N = E_N A_N P(N)^\perp$, it belongs to $\mathcal{T}(\mathcal{N})$. By Lemma 14.13, $R_A$ is contained in $\overline{R_A}_N = \overline{R_A} E_N$.

For each finite subnest $\mathcal{F} = \{0 = F_0 < F_1 < \ldots < F_n = \mathcal{N} \}$ of $\mathcal{N}$, let $A_\mathcal{F} = \sum_{j=0}^{n-1} A_{F_j}$. Then

$$A_\mathcal{F}^*A_\mathcal{F} = \sum_{j=0}^{n-1} A_{F_j}^* A_{F_j} = Q_F \leq Q .$$

Thus $\{A_\mathcal{F}\}$ is a uniformly bounded family. If $x$ is a vector in the span of a finite set of atoms $\{N_{f_j} \ominus N_j, 1 \leq j \leq n\}$, then every finite nest $\mathcal{F}$ containing $\mathcal{F}_0 = \{N_{f_j}, 1 \leq j \leq n\}$ satisfies $A_\mathcal{F}^* x = A_{\mathcal{F}_0}^* x$. Thus $\lim_{\mathcal{F}} A_\mathcal{F}^* x$ exists for a dense set of vectors. The boundedness implies that $s-\lim_{\mathcal{F}} A_\mathcal{F}^* = A^*$ exists. So $A = w-\lim_{\mathcal{F}} A_\mathcal{F}$ exists, and belongs to $\mathcal{T}(\mathcal{N})$. Moreover, by Lemma 14.18,

$$Q = s-\lim_{\mathcal{F}} Q_F = w-\lim_{\mathcal{F}} A_\mathcal{F}^* A_\mathcal{F} = A^*A \leq Q .$$

So $Q = A^*A$.

To show that $A$ is outer, it must be shown that $P(R_A)$ belongs to $\mathcal{N}'$ and $\overline{R_A} \cap N = \overline{A N}$ for all $N$ in $\mathcal{N}$. Since $\overline{R_A}_N = \overline{A_N N_+}$ is a subspace of $E_N \mathcal{H}$, it will suffice to show that $\overline{R_A} \cap N = \overline{A N} = \sum_{L \leq N} \overline{R_A}_L$. For then it is clear that $P(R_A)$ commutes with each $E_N$ and hence is in $\mathcal{N}'$. Let $S$ be the set of $N$ in $\mathcal{N}$ such that this holds. Then $S$ contains $N$ trivially. If it contains $N$, then

$$(\overline{R_A} \cap N_+) / R_A \cap N \cong \overline{R_{P(N)A}} \cap N_+$$

$$= \overline{R_{AN} + P(N_+)A} \cap E_N \mathcal{H} = \overline{R_A}_N$$
whereas
\[
\overline{AN_+/(R_A \cap N)} \approx \overline{P(N)^\perp AN_+} = \overline{E_N AN_+} = \overline{A_N N_+}.
\]
These are equal, and hence
\[
\overline{R_A \cap N_+} = \overline{AN_+} = (\overline{R_A \cap N}) \oplus R_{AN} = \sum_{L < N} \oplus \overline{R_{AL}}.
\]
So \(N_+\) belongs to \(S\). Also, if \(N\) is the sup of \(N_k\) in \(S\), then,
\[
\overline{R_A \cap N} \subset \overline{R_{P(N)A}} = \overline{\sum_{L < N} \oplus \overline{R_{AL}}} \subset \sum_{L < N} \oplus \overline{R_{AL}}
\]
whereas
\[
\overline{AN} = \bigcup_k \overline{AN_k} = \bigcup_{L < N_k} \oplus \overline{R_{AL}} = \sum_{L < N} \oplus \overline{R_{AL}}.
\]
So \(N\) belongs to \(S\). Since \(\mathcal{N}\) is well ordered, \(S = \mathcal{N}\) and thus \(A\) is outer.

Suppose that \(U\) is an operator and consider \(UQ\). This belongs to \(\mathcal{T}(\mathcal{N})\) if and only if for every \(N\) in \(\mathcal{N}\)
\[
0 = (P(N)^\perp UQ)(N) = (P(N)^\perp U A^* A)(N) = (P(N)^\perp UA^* P(N)) \overline{R_A \cap N}.
\]
Clearly, if \(UA^*\) belongs to \(\mathcal{T}(\mathcal{N})\), then \(UQ\) does also. On the other hand, if \(UQ\) belongs to \(\mathcal{T}(\mathcal{N})\), then since \(A^* P(N)\) annihilates \(N \ominus (R_A \cap N)\) it follows that \(P(N)^\perp UA^* P(N) = 0\). So \(UA^*\) belongs to \(\mathcal{T}(\mathcal{N})\).

Finally, it follows from the construction of \(Q[N,M]\) that it belongs to \(\{Q,\mathcal{N}\}'\). So by Remark 14.15, each \(A_N\) and hence \(A\) belongs to this von Neumann algebra as well. ■

It is curious that unlike results 14.2, 14.3 and 14.6, the nests for which every \(T\) in \(\mathcal{T}(\mathcal{N})\) factors as \(T = UA\) where \(U\) is inner and \(A\) is outer is not the same as for factorization of positive operators. The condition turns out to be that every element \(N\) of \(\mathcal{N}\{\mathcal{N}\}\) except 0 has an immediate successor.

**14.20 Theorem.** Let \(\mathcal{N}\) be a nest on a separable Hilbert space.

i) **If** \(N\) in \(\mathcal{N}\{0,\mathcal{N}\}\) and \(N = N_+\), then there is an operator \(T\) in \(\mathcal{T}(\mathcal{N})\) such that \(T\) does not factor as \(T = UA\) where \(U\) and \(A\) belongs to \(\mathcal{T}(\mathcal{N})\), \(A\) is outer and \(U\) is a partial isometry with \(U^* U = P(R_A)\).

ii) **If** every \(N\) in \(\mathcal{N}\{0,\mathcal{N}\}\) has an immediate successor, then every \(T\) in \(\mathcal{T}(\mathcal{N})\) has an inner-outer factorization \(T = UA\). Furthermore, the operators \(U\) and \(A\) may be taken from the von Neumann algebra \(W^*(T,\mathcal{N})\).
Proof. (i) Let $x$ be a unit vector in $N^\perp$ such that $P(N^\perp)x \neq 0$ for every $N' > N$. Let $y$ be any unit vector in $N$. Then $T = y \otimes x^*$ belongs to $T(K)$ by Lemma 3.7. If $T$ factors as $UA$, then $T^*T = x \otimes x^*$ factors as $A^*A$ with $A$ outer. This was shown to be impossible in Proposition 14.12.

(ii) If $K$ is well ordered and $T$ belongs to $T(K)$, then by Theorem 14.19 there is a factorization of $T^*T$ as $A^*A$ where $A$ is outer. Now suppose that $0$ has no immediate successor in $K$, but every $N$ in $K \setminus \{0, N\}$ does have one. Let $Q = T^*T$ and define $Q_N$ and $A_N$ as in the proof of Theorem 14.19. For each $N > 0$, one has an outer operator $B_N = \sum_{L \geq N} A_N$ in $T(K)$ which converges in the strong operator topology such that

$$B_N^*B_N = Q(N,K) \leq Q.$$ \hspace{1cm}

One has $P(N)B_M = B_N$ for $M < N$ in $K$, and the uniform boundedness ensures that

$$B = \lim_{N \to 10} B_N = \lim_{N \to 10} Q(N,K).$$ \hspace{1cm}

It must be shown that $Q(N,K)$ converges weakly to $Q$ as $N$ decreases to zero, or that $Q - Q(N,K) = Q(0,N)$ converges to zero. Now $Q(0,N)$ is the smallest positive operator which has a decomposition with respect to $N \oplus N^\perp$ of the form

$$
\begin{bmatrix}
P(N)AP(N) & P(N)QP(N) \\
P(N)QP(N) & X
\end{bmatrix}.
$$

Since $Q = T^*T$ and $T$ belongs to $T(K)$, it is easy to check that $T^*P(N)T$ has this form. Hence

$$0 \leq \lim_{N \to 10} Q(0,N) \leq \lim_{N \to 10} T^*P(N)T = 0.$$ \hspace{1cm}

Furthermore, the proof of Theorem 14.19 shows that each $B_N$ is outer and $\overline{R_B} = \sum_{L \geq N} \oplus \overline{R_L}$. Hence $\overline{R_B} = \sum_{N > 0} \oplus \overline{R_N}$ and $P(R_B)$ commutes with $K$. From this it is easy to verify that $B$ is outer. Thus $T^*T = B^*B$ has an outer factorization.

Let $T = VQ^h$ and $B = WQ^h$ be the polar decompositions and let $U = WW^*$. One has $T = UB$. Also,

$$U^*U = WV^*W^* = WP(R_Q)W^* = WW^* = P(R_A).$$

So $U^*U$ commutes with $K$. For each $N$ in $K$, one has

$$UN = U(N \cap \overline{R_B}) = U(\overline{BN}) = \overline{UBN} = \overline{TN} \subseteq N.$$ \hspace{1cm}

Hence $U$ belongs to $T(K)$, and is inner. So $T = UB$ is the desired factorization.
From Theorem 14.19, the operators $B_N$ and hence $B$ belong to the von Neumann algebra generated by $(T^*, T, K)$. The partial isometries $V$, $W$ and $U$ belong to the von Neumann algebra generated by $(T, B)$. All of these belong to $W^*(T, K)$ as claimed.

14.21 Proposition. If $N$ is a nest and $T$ in $T(N)$ has two inner outer factorizations $T = UA = VB$, then there is a partial isometry $W$ in $D(N)$ such that $WW^* = P(R_A)$, $WW^* = P(R_B)$, $B = WA$ and $V = UW$. Conversely, if $W$ is a partial isometry in $D(N)$ with $W^*W = P(R_A)$, then $B = WA$ and $V = UW^*$ yields another inner outer factorization $VB$.

Proof. Set $W = V^*U$. Since $WW^* = P(R_T) = UU^*$, $W$ is a partial isometry. As in the previous proof, one has $UN = U(N \cap \overline{R_A}) = TN$. Hence, $N \cap \overline{R_A} = U^*(TN)$. Likewise $V^*(TN) = N \cap \overline{R_B}$. Thus

$$WN = V^*(TN) = N \cap \overline{R_B} \subseteq N.$$ 

So $W$ and likewise $W^*$ belong to $T(N)$, whence $W$ is in $D(N)$. The four identities are routine.

Conversely, if $W$ is a partial isometry in $D(N)$ with initial projection onto $\overline{R_A}$, define $B = WA$ and $V = UW^*$. Then $P(R_B) = WW^*$ belongs to $D(N) = K$. For $N$ in $N$,

$$N \cap \overline{R_B} = N \cap W(\overline{R_A}) = (N \cap R_W) \cap W(\overline{R_A})$$

$$= WN \cap WR_A = W(N \cap R_A)$$

$$= W(\overline{AN}) = \overline{BN}.$$ 

Hence $B$ is outer. Also $V$ is a partial isometry in $T(N)$ with $V^*V = WW^*$, so $V$ is inner.

Notes and Remarks.

Factorization of this type was first considered by Arveson [7] for nests order isomorphic to subsets of the extended integers. In this context, he obtains Theorem 14.2 (1), Corollary 14.3, Theorem 14.20 (ii) and Proposition 14.21. He applied this to an interpolation problem dealt with in section 15.D. The results, Lemma 14.1 through Corollary 14.6, are due to Larson [4] in his paper on similarity of nests. Lemma 14.4 was proved for continuous nests by Choi and Feintuch [1]. Theorem 14.9 is due to Gohberg and Krein [2], chapter IV. However, they give a different proof of Lemma 14.8. They also obtain necessary and sufficient conditions for $I+K$ with $K$ compact to factor as in Lemma 14.7 in terms of the convergence of certain integrals. (See exercise 14.1.) The notation of inner and outer operators is due to Arveson. The results of 14.12 through 14.21 are due to Power [2, 6, 7, 9]. Lemma 14.13 is due to Lance [2].
Exercises.

14.1 (Gohberg-Krein)

(a) Consider a nest $\mathcal{K}$ and an invertible operator $T = I + K$ for $K$ compact. Show that if $T$ factors as in Theorem 14.9, then $I + P(N)KP(N)$ is invertible for every $N$ in $\mathcal{K}$.

(b) If $T$ above is self-adjoint, then $T$ factors if and only if $T$ is positive.

(c)* If $K$ is finite rank, then $T$ factors only if $I + P(N)KP(N)$ is invertible for all $N$ in $\mathcal{K}$.

(d) Extend (c) to all $K$ in $C_w$.

14.2 Let $L^2 = L^2(\mathbb{T}, dm)$ where $dm$ is normalized Lebesgue measure on the unit circle $\mathbb{T}$. This has an orthonormal basis $e_n = e^{in\theta}$, $n \in \mathbb{Z}$. Let $\mathcal{H}$ be the nest given by $0, L^2$, and $N_n = \text{span} \{e_k, k \geq n\}$. If $h$ is a bounded measurable function (i.e. $h \in L^\infty$), $M_h$ denotes the operator given by $M_h f = hf$. Note that $M_h$ belongs to $T(\mathcal{H})$ if and only if $h$ belongs to $H^\infty$. A function $h$ in $H^\infty$ is outer if $M_h N_0$ is dense in $N_0$. Show that $h$ is outer if and only if $M_h$ is an outer operator in $T(\mathcal{H})$.

14.3 Let $\mathcal{H}$ be a countable nest, and let $A$ be an outer operator in $T(\mathcal{H})$ which is bounded below. Show that there is an invertible element $B$ in $T(\mathcal{H})^{-1}$ and an isometry $U$ in $D(\mathcal{H})$ such that $A = UB$.

14.4 Show that every positive operator $Q$ in $\mathcal{B}(\mathcal{H})$ factors as $T^\ast T$ for some $T$ in $T(\mathcal{H})$ if and only if either (i) $\mathcal{H}$ is well ordered or (ii) $\mathcal{H}$ has an infinite rank atom $A$ such that if $N = N_+ \in \mathcal{H}$, then $N$ contains $A$.

14.5 (Power)

(a) Let $\mathcal{H}$ be a nest and let $A$ be an outer operator in $T(\mathcal{H})$. Suppose $X$ is an operator such that $XA$ belongs to $T(\mathcal{H})$ and $\ker X$ contains $R_k^+$. Show that $X$ belongs to $T(\mathcal{H})$.

(b) Let $\mathcal{H}$ be a well ordered nest. Show that every trace class operator $T$ in $T(\mathcal{H})$ factors as $T = A_1^+A_2$ where $A_i$ belong to $T(\mathcal{H}) \cap C_2$ and $\|T\|_1 = \|A_1\|_2 = \|A_2\|_2$.

Hint: Write $T = V |T|$ and factor $|T| = A^\ast A$.

(c) If $\mathcal{H}$ is a nest containing an element $N \neq 0$, or $\mathcal{H}$ such that $N_1 = N_+$, find a rank one operator $T$ in $T(\mathcal{H})$ which cannot be factored as $A_1A_2$ with $A_i$ in $T(\mathcal{H}) \cap C_2$.

(d)* Characterize those nests in which every trace class operator has a “Riesz” factorization as in (b).

14.6* (Larson) Characterize the compact operators $K$ such that $I + K$ is positive, invertible and factors as $TT^\ast$ for $T$ in $T(\mathcal{H})^{-1}$ for every nest $\mathcal{H}$. 
15. Reflexivity, Ideals and Bimodules

The main result of this chapter shows that the only weak* closed algebra $A$ containing a maximal abelian von Neumann algebra ( masa) such that $Lat A = M$ is a nest is $T(M)$. Then we characterize the weak* closed ideals and bimodules of a nest algebra, and show that these are single generated. (This can be read independently of the first part of this chapter.) From this we deduce that nest algebras are doubly generated as a weak* closed algebra. Then we establish a criterion for a finite set of operators to generate $T(M)$ as a norm closed left ideal. In the last part of this chapter, invariant operator ranges for nest algebras are computed.

15.A Utility Grade Tensor Products. First, the notion of a Hilbert space tensor product will be needed. Let $H_1$ and $H_2$ be Hilbert spaces. The algebraic tensor product of $H_1$ and $H_2$ consists of elements of the form $\sum_{i=1}^{n} x_i \otimes y_i$ modulo the identities

\[
x \otimes (y_1 + y_2) = x \otimes y_1 + x \otimes y_2
\]

\[
(x_1 + x_2) \otimes y = x_1 \otimes y + x_2 \otimes y
\]

and

\[
(ax) \otimes y = a(x \otimes y) = x \otimes (ay)
\]

for all $x_i$ in $H_1$, $y_i$ in $H_2$ and $a$ in $\mathbb{C}$.

An inner product is defined on elementary terms by

\[
(x_1 \otimes y_1, x_2 \otimes y_2) = (x_1, x_2)(y_1, y_2)
\]

and extending by linearity. It is routine to verify that this is well defined. It is also positive definite. To see this, consider a non-zero element $v = \sum_{i=1}^{n} x_i \otimes y_i$. Apply the Gram-Schmidt process to $\{y_i\}$ to obtain an orthonormal set $e_j$, $1 \leq j \leq m$, so that $y_i = \sum_{j=1}^{i} a_{ij} e_j$. Then

\[
v = \sum_{i=1}^{n} x_i \otimes y_i = \sum_{i=1}^{n} \sum_{j=1}^{m} a_{ij} x_i \otimes e_j
\]

\[
= \sum_{j=1}^{m} (\sum_{i=1}^{n} a_{ij} x_i) \otimes e_j = \sum_{j=1}^{m} u_j \otimes e_j.
\]
As \( v \neq 0 \), at least one \( u_j \) is non-zero. So

\[
\|v\|^2 = (v,v) = \sum_{j=1}^{m} \sum_{i=1}^{n} (u_j, u_i) (e_j, e_i) = \sum_{j=1}^{m} \|u_j\|^2 > 0 .
\]

Let \( \mathcal{H}_1 \otimes \mathcal{H}_2 \) denote the Hilbert space completion of this tensor product. Let \( \{ f_\alpha : \alpha \in A \} \) and \( \{ e_\beta : \beta \in B \} \) be orthonormal bases of \( \mathcal{H}_1 \) and \( \mathcal{H}_2 \). Then \( \{ f_\alpha \otimes e_\beta : \alpha \in A, \beta \in B \} \) is an orthonormal set in \( \mathcal{H}_1 \otimes \mathcal{H}_2 \). The closed span of these vectors contains all vectors of the form \( x \otimes e_\beta \), and hence all of the form \( x \otimes y \). Thus they span all of \( \mathcal{H}_1 \otimes \mathcal{H}_2 \) and form a basis.

Let \( S \) and \( T \) be operators in \( B(\mathcal{H}_1) \) and \( B(\mathcal{H}_2) \). Define \( S \otimes T \) in \( B(\mathcal{H}_1 \otimes \mathcal{H}_2) \) by setting \( S \otimes T(x \otimes y) = Sx \otimes Ty \) and extending by linearity to the algebraic tensor product. It is readily verified that this is well defined. To see that \( \|S \otimes T\| = \|S\| \|T\| \), consider a vector \( v = \sum_{j=1}^{n} x_i \otimes y_i \). Let \( M = \text{span} \{ y_i, Ty_i : 1 \leq i \leq n \} \), and set \( A = P(M)TP(M) \). Then \( A^*A \) is positive, and leaves \( M \) invariant. So \( M \) has an orthonormal basis \( \{ e_j : 1 \leq j \leq m \} \) consisting of eigenvectors of \( A^*A \), say \( A^*Ae_j = \lambda_j e_j \) where \( |\lambda_j| \leq \|A^*A\| \leq \|T\|^2 \). One can rewrite \( y_i = \sum_{j=1}^{m} a_{ij} e_j \), and

\[
v = \sum_{i=1}^{n} (x_i \otimes \sum_{j=1}^{m} a_{ij} e_j) = \sum_{j=1}^{m} (\sum_{i=1}^{n} a_{ij} x_i) \otimes e_j = \sum_{j=1}^{m} u_j \otimes e_j .
\]

So

\[
\|S \otimes T v\|^2 = \|\sum_{i=1}^{n} Sx_i \otimes Ty_i\|^2 = \|\sum_{i=1}^{n} Sx_i \otimes A y_i\|^2
\]

\[
= \|S \otimes A v\|^2 = \left( \sum_{j=1}^{m} Su_j \otimes Ae_j, \sum_{j=1}^{m} Su_j \otimes Ae_j \right)
\]

\[
= \sum_{j=1}^{m} \sum_{k=1}^{m} (Su_j, Su_k) (Ae_j, Ae_k) = \sum_{j=1}^{m} \lambda_j^2 (Su_j, Su_j)
\]

\[
\leq \|T\|^2 \sum_{j=1}^{m} \|Su_j\|^2 \leq \|S\|^2 \|T\|^2 \sum_{j=1}^{m} \|u_j\|^2
\]

\[
= \left( \|S\| \|T\| \|v\| \right)^2 .
\]

On the other hand, the supremum of \( \|S \otimes T(x \otimes y)\| = \|Sx\| \|Ty\| \) over unit vectors \( x \) and \( y \) is clearly \( \|S\| \|T\| \). Thus \( S \otimes T \) extends by continuity to \( \mathcal{H}_1 \otimes \mathcal{H}_2 \).

The algebraic tensor product of \( B(\mathcal{H}_1) \) and \( B(\mathcal{H}_2) \) thus is a subset of \( B(\mathcal{H}_1 \otimes \mathcal{H}_2) \). By \( B(\mathcal{H}_1) \otimes B(\mathcal{H}_2) \), we mean the weak* closure of this algebraic tensor product. This is readily seen to be all of \( B(\mathcal{H}_1 \otimes \mathcal{H}_2) \). To see this, it is enough to get a dense subset of the rank one operators. To avoid confusion, we will write a rank one operator as \( xy^* \). Consider
u = \sum_{i=1}^{n} x_i \otimes y_i$ and $v = \sum_{j=1}^{m} w_j \otimes z_j$. Then

$$uv^* = \sum_{i=1}^{n} \sum_{j=1}^{m} (x_i \otimes y_j)(w_j \otimes z_j)^*$$

$$= \sum_{i=1}^{n} \sum_{j=1}^{m} (x_i w_j^*) \otimes (y_j z_j).$$

So the rank one operator $uv^*$ is the sum of elementary operators $S_{ij} \otimes T_{ij}$. Consequently, the norm closure of $B (H_1) \otimes B (H_2)$ contains all finite rank operators, so is weak* dense in $B (H_1 \otimes H_2)$.

More generally, if $A$ and $B$ are von Neumann algebras, let $A \otimes B$ denote the weakly closed algebra generated by the elementary tensors $A \otimes B$ in $B (H_1) \otimes B (H_2)$ such that $A$ belongs to $A$ and $B$ belongs to $B$. (This is the spatial tensor product, and is not the only choice for a tensor product in general.) By abuse of notation, we may write $A \otimes I$ when we mean $A \otimes C I$. We require the following very special case of Tomita’s Commutation Theorem.

15.1 Theorem. Let $A$ be a von Neumann algebra in $B (H_1)$. Then commutant of $A \otimes B (H_2)$ is $A' \otimes CI$, and vice versa.

Proof. First, suppose that $A = CI$. Let $T$ in $B (H_1 \otimes H_2)$ commute with $I \otimes B (H_2)$. For each $y$ in $H_2$, let $P_y$ denote the projection in $B (H_2)$ onto $Cy$. Then for each $x$ in $H_1$, there is a $z$ in $H_1$ so that

$$T(x \otimes y) = T(I \otimes P_y)x \otimes y = (I \otimes P_y)T(x \otimes y) = z \otimes y.$$  

Moreover, the linearity of $T$ shows that there is a continuous linear operator $B_y$ on $H_1$ so that $T(x \otimes y) = (B_x \otimes y)$. If $y_1$ and $y_2$ are linearly independent,

$$B_{y_1+y_2}x \otimes y_1 + B_{y_1+y_2}x \otimes y_2 = B_{y_1+y_2}x \otimes (y_1+y_2)$$

$$= T(x \otimes (y_1+y_2))$$

$$= T(x \otimes y_1) + T(x \otimes y_2)$$

$$= B_{y_1}x \otimes y_1 + B_{y_2}x \otimes y_2.$$  

The independence of $y_1$ and $y_2$ implies that $B_{y_1} = B_{y_1+y_2} = B_{y_2}$. Hence there is an operator $B$ such that $T(x \otimes y) = (Bx) \otimes y = (B \otimes I)x \otimes y$ for all $x$ and $y$. Thus $T = B \otimes I$ belongs to $B (H_1) \otimes I$. On the other hand, it is clear that $B (H_1) \otimes I$ commutes with $I \otimes B (H_2)$.

In general, the commutant of $A \otimes B (H_2)$ is contained in $(I \otimes B (H_2))' = B (H_1) \otimes I$. So, an operator in this set has the form $B \otimes I$ and commutes with $A \otimes I$ for each $A$ in $A$. Hence $B$ belongs to $A'$. On the other hand, if $B$ belongs to $A'$, the $B \otimes I$ commutes with
$A \otimes X$ for every $A$ in $A$ and $X$ in $B$ ($\mathcal{H}$). So $A' \otimes I$ is the commutant of $A \otimes B$ ($\mathcal{H}$). By the Double Commutant Theorem, $A \otimes B$ ($\mathcal{H}$) is the commutant of $A' \otimes I$.

Now suppose that $\mathcal{H}_1$ is represented as $L^2(X,\mu)$ where $\mu$ is a regular Borel measure on $X$. Let $L^2(X,\mathcal{H}_2,\mu)$ denote the (equivalence classes of) Borel functions $f : X \to \mathcal{H}_2$ such that

$$\|f\|_2 = (\int \|f(x)\|^2 d\mu)^{\frac{1}{2}}$$

is finite. This is a Hilbert space, (as can be verified in the same way that completeness of $L^2(\mu)$ is proved).

15.2 Lemma. Let $(X,\mu)$ be a regular Borel measure and $\mathcal{H}_1 = L^2(X,\mu)$. Then $\mathcal{H}_1 \otimes \mathcal{H}_2$ is naturally isomorphic to $L^2(X,\mathcal{H}_2,\mu)$ via the unitary operator

$$U \sum_{i,j} a_{i,j} (e_i \otimes y_j) = \sum_{i,j} a_{i,j} f_{i,j}$$

where $\{e_i\}$ is a basis for $L^2(\mu)$, $\{y_j\}$ is a basis for $\mathcal{H}_2$ and $f_{i,j}(x) = e_i(x)y_j$.

Proof. If $f$ belongs to $L^2(\mu)$ and $f = \sum a_i e_i$, then

$$Uf \otimes y_j = U \sum_i a_i e_i \otimes y_i = \sum_i a_i f_{i,j}$$

$$= (\sum_i a_i e_i)(x) y_j = f(x) y_j.$$

So $U$ carries $L^2(\mu) \otimes \mathcal{H}_2$ isometrically onto $L^2(X,\mathcal{H}_2,\mu)$. It is easy to see that

$$L^2(\mu) \otimes \mathcal{H} = \bigoplus_j L^2(\mu) \otimes \mathcal{H}_j$$

and

$$L^2(X,\mathcal{H}_2,\mu) = \bigoplus_j L^2(X,\mathcal{H}_2,\mu).$$

So the result follows.  

Let $\mathcal{M}$ be a masa in $B(\mathcal{H})$. By Theorem 7.8, one can realize $\mathcal{M}$ as $L^\infty(X,\mu)$ acting on $L^2(X,\mu)$ for some regular Borel space $(X,\mu)$. By Lemma 15.2, we can realize $L^2(X,\mathcal{H}) \otimes \mathcal{H}$ as $L^2(X,\mathcal{H},\mu)$. There is a von Neumann algebra $L^\infty(X,B(\mathcal{H}),\mu)$ of $\mu$-essentially bounded Borel functions from $X$ into $B(\mathcal{H})$ acting on $L^2(X,\mathcal{H},\mu)$ by

$$Tf(x) = T(x)f(x).$$

15.3 Lemma. The identification between $L^2(X,\mu) \otimes \mathcal{H}$ and $L^2(X,\mathcal{H},\mu)$ of Lemma 15.2 carries $\mathcal{M} \otimes B(\mathcal{H})$ onto $L^\infty(X,B(\mathcal{H}),\mu)$.

Proof. Since $(M \otimes I)x \otimes y = (Mx) \otimes y$, it is readily verified that
for every \( f \) in \( L^2(X,\mathcal{H},\mu) \). Thus it is clear that \( L^\infty(X,B(\mathcal{H}),\mu) \) is contained in the commutant of \( U(M \otimes I)U^* \). By Theorem 15.1, \( L^\infty(X,B(\mathcal{H}),\mu) \) is contained in \( U(M \otimes B(\mathcal{H}))U^* \). On the other hand, let \( M_f \) belong to \( M \) and \( A \) belong to \( B(\mathcal{H}) \). For \( g \) in \( L^2(X,\mu) \) and \( y \) in \( \mathcal{H}_2 \)

\[
U(M_f \otimes T)(g \otimes y) = U(fg \otimes Ty) = f(g(x)Ty)
= M_{fT}(gy) = M_{fT}U(g \otimes y)
\]

where \( fT \) is the \( L^\infty \) function \( fT(x) = f(x)T \), and \( gy(x) = g(x)y \). So \( U(M_f \otimes T)U^* = M_{fT} \) belongs to \( L^\infty(X,B(\mathcal{H}),\mu) \). Thus the weakly closed algebra generated by these tensors is carried into, whence onto, \( L^\infty(X,B(\mathcal{H}),\mu) \). ■

15.B Reflexivity. The notion of reflexivity for algebras can be generalized to subspaces. A subspace \( S \) of \( B(\mathcal{H}_1,\mathcal{H}_2) \) is reflexive if

\[
S = \{ T \in B(\mathcal{H}_1,\mathcal{H}_2) : Tx \in \mathcal{H}_2 \text{ for all } x \in \mathcal{H}_1 \}
\]

Reflexive subspaces are always closed in the weak operator topology. The following lemma sets the stage.

15.4 Lemma. Let \( S \) be a weak* closed subspace of \( B(\mathcal{H}_1) \), and let \( \mathcal{H} \) be a separable Hilbert space. Then \( S \otimes I \) is a reflexive subspace of \( B(\mathcal{H}_1,\mathcal{H}) \). For each vector \( x \) in \( \mathcal{H}_1 \otimes \mathcal{H} \), let \( M_x = (S \otimes I)x \). Then for all \( T \) in \( B(\mathcal{H}_1) \),

\[
\text{dist}(T,S) = \sup_{x \in \mathcal{H}_1 \otimes \mathcal{H}, \|x\|=1} \|P(M_x)^{-1}Tx\|.
\]

Proof. Let \( \phi \) be a norm one weak* continuous linear functional annihilating \( S \). By Theorem 1.15, there is a sequence \( \{s_n, n \geq 1\} \) of positive numbers, and orthonormal sets \( \{x_n\} \) and \( \{y_n\} \) in \( \mathcal{H}_1 \) so that

\[
\sum_{n=1}^{\infty} s_n = \|\phi\| = 1 \text{ and}
\]

\[
\phi(T) = \sum_{n=1}^{\infty} s_n \langle Tx_n, y_n \rangle.
\]

Let \( \{e_n, n \geq 1\} \) be an orthonormal set in \( \mathcal{H} \). Let \( \bar{x} = \sum_{n=1}^{\infty} s_n^{\frac{1}{2}} x_n \otimes e_n \) and \( y = \sum_{n=1}^{\infty} s_n^{\frac{1}{2}} y_n \otimes e_n \) be unit vectors in \( \mathcal{H}_1 \otimes \mathcal{H} \). Then

\[
\langle (T \otimes I)\bar{x}, \bar{y} \rangle = \sum_{n=1}^{\infty} s_n \langle Tx_n, y_n \rangle = \phi(T).
\]

Let \( M_x = (S \otimes I)\bar{x} \). Now
\[ \|P(M_2) T \otimes I \| \geq \| (T \otimes I) \tilde{y} \| = |\phi(T)|. \]

Thus, by the Hahn-Banach Theorem,

\[ \text{dist}(T, S) = \sup_{\phi \in S, \|\phi\| = 1} |\phi(T)| \leq \sup_{\|\tilde{x}\| = 1} \|P(M_2) T \otimes I \| \cdot \]

On the other hand, since \( \phi(S) = 0 \), it follows that \( \tilde{y} \) is orthogonal to \( M_2 \). Therefore \( \|P(M_2) T \otimes I \| = 0 \) for \( S \in \mathcal{S} \), so

\[ \|P(M_2) T \otimes I \| = \inf_{S \in \mathcal{S}} \|P(M_2) (T - S) \otimes I \| \leq \inf_{S \in \mathcal{S}} T - S = \text{dist}(T, S). \]

Let \( A \) belong to \( B(\mathcal{H}_1 \otimes \mathcal{H}) \), and suppose that for all \( v \) in \( \mathcal{H}_1 \otimes \mathcal{H} \), one has

\[ Av \in (S \otimes I) v \subseteq B(\mathcal{H}_1 \otimes I) \subseteq B(\mathcal{H}_1 \otimes I). \]

Then \( A \) belongs to \( \text{AlgLat}(B(\mathcal{H}_1 \otimes I)) \). So \( A \) has the form \( T \otimes I \). By the previous paragraph, \( T \) belongs to \( S \). Thus \( A \) belongs to \( S \otimes I \) and hence \( S \otimes I \) is reflexive.

Note that the previous lemma applies equally well to a subspace \( S \) of \( B(\mathcal{H}_1, \mathcal{H}_2) \). Now we specialize to subspaces which are bimodules for a pair \( (M_2, M_1) \) of masas, meaning that \( M_2 M_1 \subseteq S \). This is the case, for example, if \( S = T(\mathcal{N}) \) for a nest \( \mathcal{N} \) and \( M_1 = M_2 \) is any masa containing \( \mathcal{N} \).

15.5 Lemma. Let \( M_1 \) be masas in \( B(\mathcal{H}_1) \), \( i = 1, 2 \), and let \( S \) be a subspace of \( B(\mathcal{H}_1, \mathcal{H}_2) \) which is an \( (M_2, M_1) \) bimodule. Let \( Q \) be a projection in \( M_1 \), and let \( N = S Q \mathcal{H}_1 \). Then \( P(N) \) is the least positive operator \( A \) in \( M_2 \) such that \( A \geq S Q S^* \) for all \( S \) in \( b_1(S) \).

Proof. Since \( SQ = P(N) SQ \) for all \( S \) in \( S \), it follows that for \( S \) in \( b_1(S) \) one has

\[ S Q S^* = P(N) S Q S^* P(N) \leq \|S\|^2 P(N) \leq P(N). \]

Now let \( A \) be any positive operator in \( M_2 \) such that \( A \geq S Q S^* \) for all \( S \) in \( b_1(S) \). Since \( M_2 \) is abelian, one has \( A \geq P(N) \) if and only if \( \|E A\| \geq 1 \) for any non-zero projection \( E \) in \( M_2 \) with \( E \leq P(N) \). Let \( E \) be such a projection. From the definition of \( N \), there must be a \( S \) in \( S \) so that \( E S Q \neq 0 \). Normalize so that \( \|E S Q\| = 1 \). As \( S \) is a bimodule, \( T = E S Q \) belongs to \( b_1(S) \). Hence

\[ E A = E A E \geq E T Q T^* E = T T^* \]

So \( \|E A\| \geq \|T\|^2 = 1 \), and hence \( A \geq P(N) \).
15.8 Corollary. Let \( S \) be a subspace of \( B(\mathcal{H}_1,\mathcal{H}_2) \) which is an \((\mathcal{M}_2,\mathcal{M}_1)\) bimodule. Suppose that \( \mathcal{S}y = \mathcal{H}_2 \) for every \( y \neq 0 \) in \( \mathcal{H}_1 \). Let \( B \) belong to \((\mathcal{M}_1)^+\). Then the least positive operator \( A \) in \( \mathcal{M}_2 \) such that \( A \geq SBS^* \) for all \( S \) in \( b_1(S) \) is \( A = \|B\|I \).

Proof. For \( \epsilon > 0 \), let \( Q_\epsilon \) be the spectral projection \( E_B[\|B\|^{-\epsilon},\|B\|] \). Then \( B \geq (\|B\|^{-\epsilon}) Q_\epsilon \), and \( SQ_\epsilon \mathcal{H}_1 = \mathcal{H}_2 \) since \( Q_\epsilon \neq 0 \). So if \( A \geq SBS^* \) for all \( S \) in \( b_1(S) \), then \( A \geq (\|B\|^{-\epsilon}) SQ_\epsilon S^* \). By Lemma 15.5, one has \( A \geq (\|B\|^{-\epsilon}) I \) for all \( \epsilon > 0 \). So \( A \geq \|B\|I \).

15.7 Lemma. Let \( M \) be a masa in \( B(\mathcal{H}) \). Let \( Q \) be a projection in \( M \otimes B(\mathcal{H}) \), and let \( F \) be the least projection in \( B(\mathcal{H}) \) such that \( Q \leq I \otimes F \). For each unit vector \( \xi \) in \( \mathcal{H} \), let \( E_\xi \) denote the projection onto \( \mathcal{C}\xi \), and set \( F(\xi) = \|I \otimes E_\xi \| Q(I \otimes E_\xi) \| \). Then \( I \otimes F \) is the least projection \( P \) in \( M \otimes B(\mathcal{H}) \) satisfying
\[
(I \otimes E_\xi) P(I \otimes E_\xi) \geq F(\xi) I \otimes E_\xi \quad \text{for all } \xi \in \mathcal{H}, \|\xi\| = 1.
\]

Proof. By Lemma 15.3, we can identify \( M \otimes B(\mathcal{H}) \) with \( L^\infty(X,\mathcal{B}(\mathcal{H}),\mu) \) acting on \( L^2(X,\mathcal{H},\mu) \). Thus \( Q \) is given by a function \( Q(x) \) in \( L^\infty(X,\mathcal{B}(\mathcal{H}),\mu) \), and since \( Q \) is a projection, \( Q(x) \) is a projection almost everywhere. So
\[
(I \otimes E_\xi) Q(I \otimes E_\xi) = M_{f_\xi} \otimes E_\xi
\]
where \( f_\xi(x) = (Q(x)\xi,\xi) \), and \( F(\xi) = \|f_\xi\|_\infty \). Let \( \{\xi_n\} \) be a countable dense subset of \( b_1(\mathcal{H}) \), and let \( f_n = f_{\xi_n} \). Delete a set \( X_0 \) of measure zero so that \( |f_n(x)| \leq \|f_n\|_\infty \) for \( x \in X \setminus X_0 \), \( n \geq 1 \) and \( Q(x) \) is always a projection. Let \( F_0 = \sup_{X \setminus X_0} Q(x) \). Fix \( x \in X \setminus X_0 \) and a unit vector \( \xi = Q(x)\xi \).

Choose a sequence \( \xi_n \), converging to \( \xi \). Then
\[
F(\xi) = \lim_i F(\xi_n) \geq \lim_i (Q(x)\xi_n,\xi_n) = (Q(x)\xi,\xi) = 1.
\]
Thus \( P \geq I \otimes F_0 \) and hence \( P \geq I \otimes Q(x) \) for each \( x \) in \( X \setminus X_0 \). Consequently, \( P \geq I \otimes F_0 \).

On the other hand, \( Q(x) \leq F_0 \) for \( x \) in \( X \setminus X_0 \), so \( Q \leq I \otimes F_0 \). Thus \( F_0 \geq F \). And since \( Q \leq I \otimes F \), it readily follows that \( I \otimes F \) satisfies \((*)\). By the previous paragraph, \( P \geq F_0 \). So \( F = F_0 \) and any \( P \) satisfying \((*)\) is greater than \( I \otimes F \).
15.8 Lemma. Let $\mathcal{M}_i$ be masas in $B(\mathcal{H}_1)$ and let $S$ be a subspace of $B(\mathcal{H}_1,\mathcal{H}_2)$ which is a $(\mathcal{M}_2,\mathcal{M}_1)$ bimodule. For a vector $v$ in $\mathcal{H}_1 \otimes \mathcal{H}$, let $Q$ be the projection onto $(S \otimes I)v$ and let $P$ be the projection onto $(S \otimes I)v$. For a unit vector $\xi$ in $\mathcal{H}$, let $A$ and $B$ be operators defined by $(I \otimes E_0)P(I \otimes E_0) = A \otimes E_0$ and $(I \otimes E_0)Q(I \otimes E_0) = B \otimes E_0$. Then $A$ and $B$ are positive operators in $\mathcal{M}_2$ and $\mathcal{M}_1$, respectively, and furthermore

$$A \geq SBS^*$$

for all $S$ in $b_1(S)$.

Proof. Since $P\mathcal{H}_2 = (\mathcal{M}_2 \otimes I)(S \otimes I)v$ is invariant for $\mathcal{M}_2 \otimes I$, Theorem 15.1 implies that $P$ belongs to $\mathcal{M}_2 \otimes B(\mathcal{H})$ and $A$ belongs to $(\mathcal{M}_2)_+$. Similarly, $Q$ belongs to $\mathcal{M}_1 \otimes B(\mathcal{H})$ and $B$ belongs to $(\mathcal{M}_1)_+$. For $x$ in $\mathcal{H}_2$ and $S$ in $b_1(S)$,

$$(SBS^*x,x) = ((S \otimes I)(I \otimes E_0)Q(I \otimes E_0)(S^* \otimes I)x \otimes \xi, x \otimes \xi)$$

$$= \|Q(S^* \otimes I)x \otimes \xi\|^2$$

$$= \|Q(S^* \otimes I)P(x \otimes \xi)\|^2 \leq \|P(x \otimes \xi)\|^2$$

$$= ((I \otimes E_0)P(I \otimes E_0)x \otimes \xi, x \otimes \xi) = (Ax,x).$$

Hence $A \geq SBS^*$.

15.9 Theorem. Let $\mathcal{M}_i$ be masas in $B(\mathcal{H}_1)$, and let $S$ be a subspace of $B(\mathcal{H}_1,\mathcal{H}_2)$ which is an $(\mathcal{M}_2,\mathcal{M}_1)$ bimodule. Suppose that $S_y = \mathcal{H}_2$ for every $y \neq 0$ in $\mathcal{H}_1$. Then $S$ is weak* dense in $B(\mathcal{H}_1,\mathcal{H}_2)$.

Proof. Let $v$ be any unit vector in $\mathcal{H}_1 \otimes \mathcal{H}$, and let $\xi$ be a unit vector in $\mathcal{H}$. Let $P$, $Q$, $A$, $B$ be defined as in Lemma 15.8. Thus $A \geq SBS^*$ for all $S$ in $b_1(S)$. So by Corollary 15.6, $A \geq \|B\|I$. Now

$$\|B\| = \|(I \otimes E_0)Q(I \otimes E_0)\| = F(\xi)$$

as in Lemma 15.7. So $P$ satisfies (*) of that lemma. Hence $P \geq I \otimes F$ where $F$ is the smallest projection so that $(I \otimes F)v = v$. Hence

$$\mathcal{H}_2 \otimes F \mathcal{H} \subseteq (S \otimes I)v \subseteq (B(\mathcal{H}_1,\mathcal{H}_2) \otimes I)v \subseteq \mathcal{H}_2 \otimes F \mathcal{H}.$$ 

It follows that $S \otimes I$ has the same closed ranges as $B(\mathcal{H}_1,\mathcal{H}_2) \otimes I$. By Lemma 15.4, $S$ is weak* dense in $B(\mathcal{H}_1,\mathcal{H}_2)$.

15.10 Corollary. Let $S$ be a norm closed subspace of the compact operators $K$ such that $S_y = \mathcal{H}$ for every $y \neq 0$. Suppose that $\mathcal{M}_i$ are masas such that $S$ is an $(\mathcal{M}_2,\mathcal{M}_1)$ bimodule. Then $S = K$. 

K.R. Davidson
Proof. By Theorem 15.9, $S$ is weak$^*$ dense in $B(\mathcal{H})$. If $S$ were not all of $\mathcal{K}$, there would be a continuous linear functional $\phi$ in $\mathcal{K}^*$ such that $\phi(S) = 0$. By Theorem 1.13 and 1.15, $B(\mathcal{H}) = \mathcal{K}^{**}$. The weak$^*$ closure of $S$ is annihilated by $\phi$ and thus is not all of $B(\mathcal{H})$. This contradiction establishes the corollary. \[ \blacksquare \]

In fact, this corollary is quite weak compared to what is now known about transitive algebras containing compact operators. In particular, one can drop the hypotheses about the masas. However, for subalgebras of $B(\mathcal{H})$, Theorem 15.9 is a good result. This corollary does illustrate, however, the role of duality in dealing with subalgebras of the compact operators. Corollary 15.13 below does not follow from the transitivity results.

15.11 Theorem. Let $\mathcal{H}$ be a nest, and let $\mathcal{M}$ be a masa in $T(\mathcal{H})$. Let $S$ be a subspace of $T(\mathcal{H})$ such that $\mathcal{M}S\mathcal{M} \subseteq S$ and $Sx = T(\mathcal{H})x$ for every $x$ in $\mathcal{H}$. Then $S$ is weak$^*$ dense in $T(\mathcal{H})$.

Proof. Fix $N \neq 0$ in $\mathcal{H}$. Then $P(N)SP(N)^\perp$, as a subspace of $B(N^\perp,N)$ satisfies $P(N)SP(N)^\perp y = P(N)T(\mathcal{H})P(N)^\perp y = N$ for all $y \neq 0$ in $N^\perp$. By Theorem 15.9, $P(N)SP(N)^\perp$ is weak$^*$ dense in $B(N^\perp,N)$. By Theorem 3.7, the weak$^*$ closure of $S$ contains all finite rank operators in $T(\mathcal{H})$. By the Erdos Density Theorem 3.11, $S$ is weak$^*$ dense in $T(\mathcal{H})$. \[ \blacksquare \]

15.12 Corollary. Let $\mathcal{A}$ be a weak$^*$ closed algebra containing a masa $\mathcal{M}$ such that $\text{Lat} \mathcal{A} = \mathcal{H}$. Then $\mathcal{A} = T(\mathcal{H})$.

15.13 Corollary. Let $\mathcal{A}$ be a subalgebra of the compact operator $\mathcal{K}$ such that $\text{Lat} \mathcal{A} = \mathcal{H}$. Suppose, furthermore that there is an abelian $C^*$ subalgebra $\mathcal{D}$ of $\mathcal{A}$ such that $\mathcal{D}'$ is abelian. Then $\mathcal{A} = T(\mathcal{H}) \cap \mathcal{K}$.

Proof. Let $\mathcal{A}$ be the weak$^*$ closure of $\mathcal{A}$. Then $\mathcal{A}$ contains $\mathcal{D}'' = \mathcal{D}'$ which is a masa. So $\mathcal{A} = T(\mathcal{H})$ by the previous corollary. If $\mathcal{A}$ were less than all of $T(\mathcal{H}) \cap \mathcal{K}$, the Hahn Banach Theorem implies there is a functional $\phi$ annihilating $\mathcal{A}$ but not all of $T(\mathcal{H}) \cap \mathcal{K}$. As in Corollary 15.10, this contradicts the weak$^*$ density of $\mathcal{A}$ in $T(\mathcal{H})$. \[ \blacksquare \]

Note that when considering subalgebras, instead of subspaces, one must require $\mathcal{A}$ to contain $\mathcal{M}$, not merely be a bimodule. For example, if $\mathcal{H}$ is a maximal atomic nest and $\mathcal{A} = \{T \in T(\mathcal{H}) : \Delta(T) = 0\}$, then $\mathcal{MAM} = \mathcal{A}$ and $\text{Lat} \mathcal{A} = \mathcal{H}$, but $\mathcal{A} = \mathcal{A}^{**} \neq T(\mathcal{H})$. However, one has $\mathcal{AN} = N_{\mathcal{H}} = N_{\mathcal{H}}$ for countably many $N$ in $\mathcal{H}$. So as a subspace, $\mathcal{A}$ is distinguished from $T(\mathcal{H})$ by its ranges.
15.C Weak* Closed Ideals. Let $\mathcal{H}$ be a nest, and let $S$ be a weak* closed $\mathcal{T}(\mathcal{H})$ bimodule (i.e., $\mathcal{T}(\mathcal{H})S\mathcal{T}(\mathcal{H}) = S$). For each $N$ in $\mathcal{H}$, $\widetilde{N} = \overline{SN}$ is invariant for $\mathcal{T}(\mathcal{H})$ and hence belongs to $\mathcal{H}$. Moreover, $0 = 0$, $N \leq N'$ implies $\widetilde{N} \leq \widetilde{N'}$, and if $N = \sup N_k$, then $\widetilde{N} = \sup \widetilde{N}_k$. So the map $\Phi(N) = \widetilde{N}$ is a left continuous, order homomorphism of $\mathcal{H}$ into itself. On the other hand, given such a map $\Phi$, the set

$$S_\Phi = \{ T \in \mathcal{T}(\mathcal{H}) : TN \subseteq \Phi(N) \text{ for all } N \text{ in } \mathcal{H} \}$$

is a $\mathcal{T}(\mathcal{H})$ bimodule. It is a routine exercise to verify that $\overline{S_\Phi N} = \Phi(N)$.

15.14 Theorem. Every weak* closed $\mathcal{T}(\mathcal{H})$ bimodule $S$ has the form $S_\Phi$, where $\Phi$ is the left continuous order homomorphism of $\mathcal{H}$ into itself with $\Phi(0) = 0$ given by $\Phi(N) = \overline{SN}$.

Proof. Clearly, $S$ is contained in $S_\Phi$; so it suffices to prove that $S_\Phi$ is contained in $S$. Fix $T$ in $S_\Phi$. By the Erdos Density Theorem 3.10, there is a net $F_\alpha$ of finite rank contractions in $\mathcal{T}(\mathcal{H})$ converging to $I$ in the * strong topology. So $TF_\alpha$ belong to $S_\Phi$ and converge to $T$ in the * strong topology. By Proposition 3.8, $F_\alpha$ is the sum of rank one operators in $\mathcal{T}(\mathcal{H})$. So $TF_\alpha$ is the sum of operators of the form $TR$ where $R$ is a rank one operator in $\mathcal{T}(\mathcal{H})$. It suffices, then, to show that all such operators belong to $S$.

Let $x \otimes y^*$ be a rank one operator in $\mathcal{T}(\mathcal{H})$. Let $N$ be the element of $\mathcal{H}$ provided by Lemma 3.7 such that $x$ belongs to $N$ and $y$ belongs to $(N_\perp)^{-1}$. Then $Tx$ belongs to $\Phi(N) = \overline{SN}$. So there are operators $S_\sigma$ in $S$ such that $\lim S_\sigma x = Tx$. Hence $\lim S_\sigma x \otimes y^* = Tx \otimes y^*$ belongs to $S$. Thus $S = S_\Phi$ by the argument of the previous paragraph. $
$

Now we consider the question of generators. Notice that if you are only interested in $S$ as a $\mathcal{T}(\mathcal{H})$ bimodule, you do not need the previous section on reflexivity.

15.15 Theorem. Let $\mathcal{H}$ be a nest on a separable space, and let $\mathcal{M}$ be a masa containing $\mathcal{H}''$. Then every $\mathcal{T}(\mathcal{H})$ bimodule is singly generated as an $\mathcal{M}$ bimodule.

Proof. Let $S$ be a $\mathcal{T}(\mathcal{H})$ bimodule, and set $\Phi(N) = \overline{SN} \equiv \widetilde{N}$ for $N$ in $\mathcal{H}$. By Theorem 15.14, $S = S_\Phi$. The weak* closed $\mathcal{M}$ bimodule generated by $S$ is $S_0 = \overline{MSM^*}$. For this to equal $S$, it is necessary that for every vector $x$,

$$\overline{Sx} = \overline{S_0 x} = \overline{MSMx} .$$

By Theorem 15.14, this is also sufficient to show that $S$ generates $S$ as a $\mathcal{T}(\mathcal{H})$ bimodule. To see that this suffices as an $\mathcal{M}$ bimodule, fix $N$ in $\mathcal{H}$.
and consider $P(\hat{N})S_0 P(N_-)^\perp$ as a subspace of $B(N_-, \hat{N})$. For every $x$ in $N_-$,  

$$
P(\hat{N})S_0 P(N_-)^\perp x = P(\hat{N})Sx = P(\hat{N})S\overline{T(N)x} = P(\hat{N})S\overline{N} = P(\hat{N})N_-
$$

By Theorem 15.9, $P(\hat{N})S_0 P(N_-)^\perp$ equals $B(N_-, \hat{N})$. In particular, $S_0$ contains every rank one operator in $S$. So by the proof of Theorem 15.14, $S_0 = S$.

Now we construct an operator $S$ with this property. If $E$ is a projection $\mathcal{M}$, one can always find a vector $x$ with $\text{supp}(x) = E$ (in $\mathcal{M}$) in the sense that $Ex = x$ but $Fx \neq x$ for any projection $F < E$ in $\mathcal{M}$. By Proposition 2.13, $\mathcal{M}$ is compact and metrizable in the order topology and has countably many atoms. So there is a sequence $\{N_k, k \geq 0\}$ of distinct elements of $\mathcal{M}$ which is dense in the order topology, $N_0 = \{0\}$, $N_1 = \mathcal{M}$, and which contains the endpoints of every atom. For $k \geq 2$, there are unique integers $i = i(k)$ and $j = j(k)$ such that $0 \leq i, j \leq k-1$, $N_i < N_k < N_j$, and if $0 \leq \ell \leq n-1$, then $N_\ell \leq N_i$ or $N_\ell \geq N_j$.

Now we define $S$. If $\mathcal{M}_- \neq \mathcal{M}$, choose unit vectors $e_1$ and $f_1$ so that $\text{supp}(e_1) = P(\hat{N})$ and $\text{supp}(f_1) = P(\mathcal{M}_-)$. For $k \geq 2$, choose unit vectors $e_k$ and $f_k$ so that  

$$
\text{supp}(e_k) = P(\hat{N}_k)P(\hat{N}_{i(k)})^\perp \quad \text{and} \quad \text{supp}(f_k) = P(N_{k-})^\perp P(N_{j(k)-})
$$

Set $S_k = 2^{-k}e_k \otimes f_k$ and $S = \sum_{k=1}^\infty S_k$. Fix $k$, $i = i(k)$ and $j = j(k)$ and consider  

$$
P(\hat{N}_i)^\perp P(\hat{N}_k)SP(N_{k-})^\perp P(N_{j-})
$$

For $\ell < k$ and $N_{k-} \leq N_i$, $P(\hat{N}_i)^\perp S_\ell = 0$; and $\ell < k$ and $N_{k-} \geq N_j$ implies $S_\ell P(N_{j-}) = 0$. For $\ell > k$ and $N_{i(k)} < N_k$, $N_{i(k)} \leq N_k$ so $S_\ell P(N_{k-})^\perp = 0$; and if $\ell > k$ and $N_{i(k)} \geq N_k$, then $N_{i(k)} \geq N_k$ so $P(\hat{N}_k)S_\ell = 0$. Consequently,  

$$
P(\hat{N}_i)^\perp P(\hat{N}_k)SP(N_{k-})^\perp P(N_{j-}) = S_k
$$

Hence $S_0 = \overline{M^*SM^*}$ contains each $S_k$ for $k \geq 1$.

Let $x$ be a non-zero vector and let $E$ be the projection onto $M^*x$. Let $N$ be the least element of $\mathcal{M}$ such that $E \leq P(N)$. Then $Sx = \hat{N}$ and $S_0x = S_0E\mathcal{M}$. If $N \neq N_-$, then $N = N_k$ for some $k$ and $P(N_-)^\perp E \neq 0$. Thus $Ex_k \neq 0$, so $S_0E\mathcal{M}$ contains $S_kEx_k$ which is a non-zero multiple of $y_k$ with support $P(\hat{N}_{i(k)})^\perp P(\hat{N}_k)$. Likewise, $Ex_{i(k)}(k) \neq 0$ and $S_0E\mathcal{M}$ contains a non-zero multiple of $y_{i(k)}$ with support $P(\hat{N}_{i(k)})^\perp P(\hat{N}_k)$. In at most $k$ steps, one obtains vectors in $S_0E\mathcal{M}$ with joint support equal to $P(\hat{N})$.

Now suppose $N = N_-$. Recursively define a sequence $k_n$ by setting $k_1 \geq 1$ to be the least integer such that $N_{k_1} < N$; and $k_{n+1}$ is the least integer so that $k_{n+1} > k_n$ and $N_{k_n} < N_{k_{n+1}} < N$. So $i(k_{n+1}) = k_n$ (and
$k_0 = 0$) and $N_{j(k_n)} \geq N$ for every $n$. Since $\{N_n\}$ is dense in $\mathcal{H}$, one has
\[ \sup N_{k_n} = N. \]
From the definition of $N$, one has $E \bar{P}(N_{k_n}) P(N) \neq 0$ and hence $E x_{k_n} \neq 0$. As above, we obtain that $S_0 E \mathcal{H}$ contains $y_{k_n}$, which has support
\[ P(\bar{N}_{k_n}) P(\bar{N}_{i(k_n)}) = P(\bar{N}_{k_n}) P(\bar{N}_{k_{n-1}}). \]
Jointly, these vectors have support $\sup P(\bar{N}_{k_n}) = P(\bar{N})$. As $S_0 E \mathcal{H}$ is $\mathcal{M}$ invariant, it must be all of $\bar{N} = \bar{x}$.

Thus it has been established that $S$ generates $S$ as an $\mathcal{M}$ bimodule.

15.16 Corollary. Every weak* closed ideal in $T(\mathcal{H})$ is principal.

Proof. Immediate.

15.17 Corollary. $T(\mathcal{H})$ is doubly generated as a weak* closed algebra.

Proof. Let $\mathcal{M}$ be a masa containing $\mathcal{H}''$. By Remark 7.5, there is a positive operator $A$ such that $\mathcal{M}$ is the weak* closed algebra generated by $A$. Since $T(\mathcal{H})$ is a bimodule over itself, it is singly generated as an $\mathcal{M}$ bimodule by some operator $T$. The weak* closed algebra generated by $A$ and $T$ contains $\mathcal{M}$, so is an $\mathcal{M}$ bimodule contained in $T(\mathcal{H})$ containing $T$. So it equals $T(\mathcal{H})$.

15.D Interpolation. A well known problem in Banach algebras is determining when a finite set $A_1,...,A_n$ generate the algebra as a left ideal. This is equivalent to the existence of elements $B_1,...,B_n$ such that $\sum_{i=1}^n B_i A_i = I$.

In a $C^*$-algebra, it is easy to verify that a necessary and sufficient condition is that $\sum_{i=1}^n A_i^* A_i$ be invertible, or equivalently, that there is an $\varepsilon > 0$ so that
\[ \sum_{i=1}^n \| A_i x \|^2 \geq \varepsilon \| x \|^2 \quad \text{for all } x \in \mathcal{H}. \]

In a nest algebra, this is necessary but not sufficient. For example, let $\mathcal{N} = \{(0), \mathbb{C} e_1, \mathbb{C}^2\}$ be the standard nest on $\mathbb{C}^2 = \text{span} \{e_1, e_2\}$. Let $A_1 = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}$ and $A_2 = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}$. Now $A_1^* A_1 + A_2^* A_2 = I$, but if $B_1$ and $B_2$ are upper triangular, then $(B_1 A_1 + B_2 A_2)^* e_2 = 0$.

Further necessary conditions are obtained as follows: Suppose $\sum_{i=1}^n B_i A_i = I$ and let $N$ belong to $\mathcal{M}$. Since compression to $N_{\perp}$ is a homomorphism (Proposition 2.15),
\[ \sum_{i=1}^{n} P(N)^{\perp} B_i P(N)^{\perp} A_i P(N)^{\perp} = P(N)^{\perp}. \]

Applying this to a vector \( x \) yields
\[ \| P(N)^{\perp} x \| \leq \sum_{i=1}^{n} \| B_i \| \| P(N)^{\perp} A_i x \| \]
\[ \leq (\sum_{i=1}^{n} \| B_i \|)^{\frac{1}{2}} (\sum_{i=1}^{n} \| P(N)^{\perp} A_i x \|^{2})^{\frac{1}{2}} \]
\[ = (\sum_{i=1}^{n} \| B_i \|^{3})^{\frac{1}{2}} (\sum_{i=1}^{n} A_i^{*} P(N)^{\perp} A_i x, x) . \]

Thus one obtains \( \sum_{i=1}^{n} A_i^{*} P(N)^{\perp} A_i \geq \epsilon P(N)^{\perp} \), or equivalently
\[ \sum_{i=1}^{n} \| P(N)^{\perp} A_i x \|^{2} \geq \epsilon^{2} \| P(N)^{\perp} x \|^{2} \]
for all \( x \) in \( \mathcal{H} \) and \( N \) in \( \mathcal{H} \), where \( \epsilon = (\sum_{i=1}^{n} \| B_i \|^{3})^{\frac{1}{6}} > 0 \). It will be shown that this is sufficient.

15.18 Lemma. Let \( A \) be a partial isometry in \( \mathcal{T}(\mathcal{H}) \) such that \( D_A = A^{*}A \) belongs to \( \mathcal{H}^{\prime} \) (an inner operator 14.11). Suppose \( \epsilon > 0 \) and \( \| P(N)^{\perp} Ax \| \geq \epsilon \| P(N)^{\perp} x \| \) for all \( N \) in \( \mathcal{H} \) and \( x \) in \( D_A \mathcal{H} \), the initial space of \( A \). Then there is an operator \( B \) in \( \mathcal{T}(\mathcal{H}) \) so that \( BA = D_A \).
Moreover, \( \| B \| \leq 4\epsilon^{-2} \).

Proof. For \( N \) in \( \mathcal{H} \) and \( x \) in \( D_A \mathcal{H} \),
\[ \| P(N)A P(N)^{\perp} x \|^{2} = \| A P(N)^{\perp} x \|^{2} - \| P(N)^{\perp} A P(N)^{\perp} x \|^{2} \]
\[ \leq (1-\epsilon^{2}) \| x \|^{2} . \]

On the other hand, if \( x \) is in \( D_A^{\perp} \mathcal{H} \), \( P(N)A P(N)^{\perp} x = 0 \). Thus by Arveson's Distance Formula (Theorem 9.5),
\[ \text{dist}(A^{*}, \mathcal{T}(\mathcal{H})) = \sup_{N \in \mathcal{H}} \| P(N)^{\perp} A^{*} P(N) \| \leq (1-\epsilon^{2})^{\frac{1}{6}} . \]

Choose \( C \) in \( \mathcal{T}(\mathcal{H}) \) so that \( \| A^{*} - C \| \leq (1-\epsilon^{2})^{\frac{1}{6}} \). Without loss of generality, we may suppose that \( C = D_A C \). Let \( T = I - D_A + CA \). Then
\[ \| I - T \| = \| A^{*} A - C A \| \leq \| A^{*} - C \| \leq (1-\epsilon^{2})^{\frac{1}{6}} < 1 \]

So \( T^{-1} \) belongs to \( \mathcal{T}(\mathcal{H}) \) and \( \| T^{-1} \| \leq (1 - (1-\epsilon^{2})^{\frac{1}{6}})^{-1} \). Let \( B = T^{-1} C \). Then
\[ BA = T^{-1}CA = (I-D_A+CA)^{-1}(I-D_A+CA-I+D_A) \]
\[ = I-(I-D_A+D_A^2C_AD_A)^{-1}(I-D_A) = D_A. \]

Finally, \( \|B\| \leq (1-(1-\epsilon^2)^{1/2})(1+(1-\epsilon^2)^{1/2}) \leq (2\epsilon^{-2})^{-1} = 4\epsilon^{-2}. \]

**15.19 Theorem.** Let \( \mathcal{N} \) be a nest, let \( \epsilon > 0 \), and let \( A_1, \ldots, A_n \) be operators in \( T(\mathcal{N}) \) satisfying
\[ \sum_{i=1}^{n} \|P(N)^{-1}A_i x\|^2 \geq \epsilon^2 \|P(N)^{-1}x\|^2 \]
for all \( x \) in \( \mathcal{N} \) and \( N \) in \( \mathcal{N} \). Then there are operators \( B_1, \ldots, B_N \) in \( T(\mathcal{N}) \) such that \( \sum_{i=1}^{n} B_i A_i = I \). Moreover, if \( \|A_i\| \leq 1 \) for all \( i \), one may take \( \|B_i\| \leq 4n\epsilon^{-3} \) for \( 1 \leq i \leq n \).

**Proof.** Scale each \( A_i \) so that \( \|A_i\| \leq 1 \), and adjust \( \epsilon \) if necessary. First suppose that \( \mathcal{N} \) is a finite nest. Since \( \sum_{i=1}^{n} A_i^* A_i \geq \epsilon^2 I \), Theorem 14.2 provides an invertible element \( C \) of \( T(\mathcal{N}) \) so that \( C^* C = \sum_{i=1}^{n} A_i^* A_i \). Hence \( A_i = A_i C^{-1} \) satisfy \( \sum_{i=1}^{n} A_i^* A_i = I \). Now
\[ \|C\|^2 \leq \sum_{i=1}^{n} \|A_i\|^2 \leq n, \]
so
\[ \|P(N)^{-1}x\|^2 \geq \epsilon^2 \|P(N)^{-1}C^{-1}P(N)^{-1}x\|^2 \]
\[ \leq \|C\|^2 \|P(N)^{-1}C^{-1}P(N)^{-1}x\|^2 \]
\[ \leq n\epsilon^2 \|P(N)^{-1}C^{-1}P(N)^{-1}x\|^2 \]

Hence
\[ \sum_{i=1}^{n} \|P(N)^{-1}A_i C^{-1}x\|^2 \geq \epsilon^2 \|P(N)^{-1}C^{-1}x\|^2 \geq \frac{\epsilon^2}{n} \|P(N)^{-1}x\|^2. \]

So \( A_i \) satisfy the same hypotheses with \( \epsilon' = \epsilon n^{-1} \).

Consider the Hilbert space \( \mathcal{H}^{(n)} = \mathcal{H} \otimes \mathcal{C}^n \). Then \( B(\mathcal{H}^{(n)}) = B(\mathcal{H}) \otimes \mathcal{M}_n \) is the algebra of \( n \times n \) matrices with entries in \( B(\mathcal{H}) \). The nest \( \mathcal{H}^{(n)} \) gives rise to the nest algebra \( T(\mathcal{H}^{(n)}) = T(\mathcal{N}) \otimes \mathcal{M}_n \). This algebra contains the operator
\[ A = \begin{bmatrix} A_1 & 0 & \cdots & 0 \\ A_2 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ A_n & 0 & \cdots & 0 \end{bmatrix} \]
Now \( A^* A \) is a projection which commutes with \( \mathcal{M}_n \). So \( A \)
is inner. Moreover,
\[
A^*P(N^{(n)})^\perp A = \begin{bmatrix}
\sum_{i=1}^{n} A_i^* P(N) A_i^* & 0 & 0 \\
0 & 0 & 0 \\
0 & 0 & 0
\end{bmatrix} \geq (\varepsilon^2) D_A P(N^{(n)})^\perp.
\]

So by Lemma 15.18, there is an operator \( B \) in \( T(\mathcal{M}^{(n)}) \) so that \( BA = D_A \).

The first row of the \( n \times n \) matrix is \( \begin{bmatrix} B_1 \ldots B_n \end{bmatrix} \) which yields \( \sum_{i=1}^{n} B_i A_i^* = I \).

The norm condition \( \|B\| \leq 4(\varepsilon^2)^{-2} = 4n \varepsilon^{-2} \) implies the same condition for each \( B_i \). Let \( B_i = C^{-1} B_i \), so \( \|B_i\| \leq 4n \varepsilon^{-3} \). Then
\[
\sum_{i=1}^{n} B_i A_i = C^{-1} (\sum_{i=1}^{n} B_i A_i^*) C = I.
\]

Now turn to a general nest \( \mathcal{M} \). For each finite subnest \( \mathcal{F} \), there are operators \( B_i^\mathcal{F} \) in \( T(\mathcal{F}) \) with \( \|B_i^\mathcal{F}\| \leq 4n \varepsilon^{-3} \) and \( \sum_{i=1}^{n} B_i^\mathcal{F} A_i = I \). Thus the set
\[
B_\mathcal{F} = \{(B_1, \ldots, B_n) \in T(\mathcal{F})^{(n)} : \sum_{i=1}^{n} B_i A_i = I, \|B_i\| \leq 4n \varepsilon^{-3}\}
\]
is a non-empty set which is compact in the weak* topology (because multiplication by fixed operators is weak* continuous). Since
\[
B_\mathcal{F}_1 \cap \ldots \cap B_\mathcal{F}_n = B_\mathcal{F}
\]
where \( \mathcal{F} \) is the nest \( \bigcup_{i=1}^{n} \mathcal{F}_i \), these sets have the finite intersection property. Thus by compactness, the intersection over all finite subnests is non-empty. Let \( (B_1, \ldots, B_n) \) be an element of this intersection. Then \( \sum_{i=1}^{n} B_i A_i = I, \|B_i\| \leq 4n \varepsilon^{-3} \), and each \( B_i \) belongs to \( T(\mathcal{F}, \mathcal{M}) \) for every \( \mathcal{N} \) in \( \mathcal{M} \), and thus belongs to \( T(\mathcal{M}) \).

**15.E Invariant Operator Ranges.** An operator range is the (non-closed) range of a bounded operator. The operator ranges invariant for an algebra forms a lattice under sums and intersection which is usually bigger than the invariant subspace lattice, and hence contains more information. In this section, the invariant operator ranges of a nest algebra will be computed.

The operator ranges in \( \mathcal{M} \) are of the form \( A \mathcal{M}' \) where \( A \) belongs to \( B(\mathcal{M}', \mathcal{M}) \). But clearly there is no loss of generality in taking \( \mathcal{M}' = \mathcal{M} \). Also the range \( R(A) = R(AA')^\perp \), so one may always take \( A \) to be positive. On the other hand, it is often convenient to restrict \( A \) to \( (\ker A)^\perp \), so that it has the same range but is also one to one.
15.20 Lemma. The operator ranges of \( \mathcal{H} \) form a lattice. Moreover

\[
\mathcal{R}(A) + \mathcal{R}(B) = \mathcal{R}((AA^*+BB^*)^\mathcal{H}) = \mathcal{R}\begin{bmatrix} A & B \\ 0 & 0 \end{bmatrix} \cap (\mathcal{H} \oplus 0)
\]

\[
\mathcal{R}(A) \cap \mathcal{R}(B) = \mathcal{R}((AXA^*)^\mathcal{H})
\]

where \( X = P(\mathcal{H})P | \mathcal{H} \) and \( P \) is the projection in \( \mathcal{B}(\mathcal{H} \oplus \mathcal{H}) \) onto \( \ker \begin{bmatrix} A & B \\ 0 & 0 \end{bmatrix} \).

Proof. Let \( T = \begin{bmatrix} A & B \\ 0 & 0 \end{bmatrix} \). It is clear that \( \mathcal{R}(T) = (\mathcal{R}(A) + \mathcal{R}(B)) \oplus 0 \).

This equals \( \mathcal{R}((TT^*)^\mathcal{H}) = \mathcal{R}((AA^*+BB^*)^\mathcal{H} \oplus 0) \). Let \( P = \begin{bmatrix} X & Z \\ Z^* & Y \end{bmatrix} \) be the projection onto \( \ker T \). then \( 0 = TP \) implies \( AX = -BZ^* \) and \( AZ = -BY \). So

\[
\mathcal{R}(AX) + \mathcal{R}(AZ) = \mathcal{R}(BZ^*) + \mathcal{R}(BY) \subseteq \mathcal{R}(A) \cap \mathcal{R}(B).
\]

On the other hand, if \( w = Au = Bv \), then \( \begin{bmatrix} u \\ -v \end{bmatrix} \) belongs to \( \ker T \). So

\[
\begin{bmatrix} u \\ -v \end{bmatrix} = P \begin{bmatrix} u \\ -v \end{bmatrix} = \begin{bmatrix} Xu-Zv \\ Z^u-Yv \end{bmatrix}.
\]

Thus \( w = A(Xu-Zv) = AXu-AZv \) belongs to \( \mathcal{R}(AX) + \mathcal{R}(AZ) \). Hence

\[
\mathcal{R}(A) \cap \mathcal{R}(B) = \mathcal{R}(AX) + \mathcal{R}(AZ) = \mathcal{R}((AXA^*+ZZ^*)A^\mathcal{H})
\]

\[
= \mathcal{R}((AXA^*)^\mathcal{H})
\]

since \( P = P^2 \) implies \( XX^* + ZZ^* = X \).

The first main result is to find the algebras with no proper invariant operator ranges. For technical reasons, certain unbounded operators will be considered. Let \( \mathcal{D}(X) \) denote the domain of a linear map, and write \( X \subset Y \) to mean \( \mathcal{D}(X) \subset \mathcal{D}(Y) \) and \( Xx = Yx \) for all \( x \) in \( \mathcal{D}(X) \).

15.21 Lemma. Let \( S \) be a set of operators with no proper invariant operator ranges. Suppose that \( X \) is a linear map such that the graph \( \mathcal{G}(X) = \{ x \oplus Xx : x \in \mathcal{D}(X) \} \) is an operator range and such that \( SX \subset XS \) for all \( S \) in \( S \). Then \( X \) is a scalar multiple of the identity.

Proof. Let \( A \) be an injective operator in \( B(\mathcal{H}, \mathcal{H} \oplus \mathcal{H}) \) with range \( \mathcal{G}(X) \), and let \( P_1(P_2) \) be the projection of \( \mathcal{H} \oplus \mathcal{H} \) onto its first (second) coordinate. Then \( \mathcal{D}(X) = \mathcal{R}(P_1A) \) is an operator range which is invariant for \( S \). Thus \( \mathcal{D}(X) = \mathcal{H} \). So \( P_1A \) is a bounded bijection and hence has a bounded
inverse by Banach's Open Mapping Theorem. Thus \( X = P_x A P_1 A^{-1} \) is bounded. The identity \( SX = XS \) for \( S \) in \( \mathcal{S} \) implies that \( R(X) \) is an invariant range for \( S \), so equals 0 or \( \mathcal{H} \). Choose \( \lambda \) so that \( X - \lambda I \) is not invertible and hence \( R(X - \lambda I) \neq \mathcal{H} \). As \( R(X - \lambda I) \) is also invariant for \( S \), it must equal \( \{0\} \); so \( X = \lambda I \).

The next lemma is the weak operator topology analogue of Lemma 15.4.

**15.22 Lemma.** Let \( S \) be a unital subalgebra of \( B(\mathcal{H}) \). An operator \( A \) belongs to the weak operator closure of \( S \) if and only if \( A^{(n)} \) belongs to \( AlgLat S^{(n)} \) for all \( n \geq 1 \).

**Proof.** Let \( \phi(T) = \sum_{j=1}^{n} (Tx_j, y_j) \) be a weakly continuous function annihilating \( S \). Let \( x = (x_1,\ldots,x_n) \) and \( y = (y_1,\ldots,y_n) \) be vectors in \( \mathcal{H}^{(n)} \). Clearly \( (S^{(n)}x, y) = 0 \) for all \( S \) in \( S \). So \( M = S^{(n)}x \) is an invariant subspace of \( S^{(n)} \) containing \( x \) and orthogonal to \( y \). If \( A^{(n)} \) belongs to \( AlgLat S^{(n)} \) for all \( n \geq 1 \), then

\[
(A^{(n)}x, y) = (P(M)^{\perp}A^{(n)}P(M)x, y) = 0.
\]

So by the Hahn-Banach Theorem, \( A \) belongs to \( S^{\text{wot}} \). The converse is clear.

**15.23 Lemma.** Let \( S \) be a unital algebra with no invariant operator ranges. Let \( L \) be an invariant operator range for \( S^{(n)} \) which contains a vector \( x_1 \oplus \cdots \oplus x_n \) with linearly independent components. Then \( L = \mathcal{H}^{(n)} \).

**Proof.** The case \( n = 1 \) is given by hypothesis. Assume it is valid for all \( m < n \). If \( L \) contains a vector \( 0 \oplus \cdots \oplus 0 \oplus x_n \) with \( x_n \neq 0 \), then

\[
L_n = \{ y \in \mathcal{H}: 0 \oplus \cdots \oplus 0 \oplus y \in L \cap 0 \oplus \cdots \oplus 0 \oplus \mathcal{H} \}
\]

is a non-zero operator range for \( S \). Thus \( L_n = \mathcal{H} \). So \( L = L' \oplus L_n \) where \( L' = \{ y \in \mathcal{H}^{(n-1)}: y \oplus 0 \in L \} \) is an invariant operator range for \( S^{(n-1)} \). Now \( L' \) contains \( x_1 \oplus \cdots \oplus x_{n-1} \), so by the induction hypothesis, \( L' = \mathcal{H}^{(n-1)} \) whence \( L = \mathcal{H}^{(n)} \).

Suppose on the other hand that \( L_n = \{0\} \). Let \( L' \) be the projection of \( L \) onto the first \( n-1 \) coordinates. Then there is a linear map \( X' \) of \( L' \) into \( \mathcal{H} \) so that \( L = \{ y \oplus Xy: y \in L' \} \). Hence

\[
S^{(n)}(y \oplus Xy) = S^{(n-1)}y \oplus SXy = S^{(n-1)}y \oplus XS^{(n-1)}y.
\]

In particular, \( L' \) is an invariant operator range for \( S^{(n-1)} \) containing \( x_1 \oplus \cdots \oplus x_{n-1} \). By induction, \( L' = \mathcal{H}^{(n-1)} \). Therefore there are linear maps \( X_i \) of \( \mathcal{H} \) into \( \mathcal{H} \) so \( X_i(y_1,\ldots,y_{n-1}) = \sum_{i=1}^{n-1} X_i y_i \). It follows that
$M_k = \{ y \oplus \sum_{i=1}^{n-1} x_i y : y \in \mathcal{D}(\mathcal{H}) \}$ is an invariant operator range for $\mathcal{S}(\mathcal{H})$ (unitarily equivalent to the intersection of $L$ with $0 \oplus \ldots \oplus \mathcal{H} \oplus 0 \oplus \ldots \oplus \mathcal{H}$). By Lemma 15.21, $X_i = \lambda_i I$. Thus $x_n = \sum_{i=1}^{n-1} \lambda_i x_i$ for every $(x_1, \ldots, x_n)$ in $L$.

This is contrary to hypothesis, so this case does not occur.

15.24 Theorem. Let $S$ be a weakly closed, unital algebra with no proper invariant operator ranges. Then $S = B(\mathcal{H})$.

**Proof.** Let $A$ belong to $B(\mathcal{H})$. Let $x = x_1 \oplus \ldots \oplus x_n$ be a vector in $\mathcal{Y}(\mathcal{H})$, and let $M = \mathcal{S}(\mathcal{H}) x$ be the smallest invariant subspace containing $x$. Without loss of generality, one may assume that $x_1, \ldots, x_k$ are linearly independent and $x_j = \sum_{i=1}^{k} c_{ji} y_i$ for $k+1 \leq j \leq n$. Let $L$ be the projection of $M$ onto $\mathcal{Y}(\mathcal{H})$. This is an invariant operator range of $\mathcal{S}(\mathcal{H})$. So Lemma 15.23 implies $L = \mathcal{Y}(\mathcal{H})$. Hence $M$ equals

$$\{ y_1 \oplus \ldots \oplus y_n : y_i \in \mathcal{H}, 1 \leq i \leq k, y_j = \sum_{i=1}^{k} c_{ji} y_i, k+1 \leq j \leq n \}.$$ 

Clearly, this is invariant for $A(\mathcal{H})$. By Lemma 15.22, $A$ belongs to $S$. But $A$ was arbitrary, so $S = B(\mathcal{H})$.

Now consider a norm closed unital algebra that does have invariant operator ranges.

15.25 Lemma. Let $S$ be a closed unital algebra, and let $A$ be an injective operator in $B(\mathcal{H}', \mathcal{H})$ so that $A \mathcal{H}'$ is invariant under $S$. Then there is a continuous representation $\pi$ of $S$ in $B(\mathcal{H}')$ so that $S A = A \pi(S)$ for all $S$ in $S$.

**Proof.** For each $x$ in $\mathcal{H}'$ and $S$ in $S$, $S A x$ belongs to $A \mathcal{H}'$ and hence there is a unique vector $y = y(S, x)$ in $\mathcal{H}'$ so that $A y = S A x$. The uniqueness forces $y(S, x)$ to be linear in both variables. Thus for each $S$, there is a linear map $\pi(S) x = y(S, x)$ which is everywhere defined. It will be shown that $\pi(S)$ is closed, and hence is bounded by the Closed Graph Theorem. So suppose that $\lim x_n = 0$ and $\lim \pi(S) x_n = y_0$. Then

$$A y_0 = \lim_{n \to \infty} A \pi(S) x_n = \lim_{n \to \infty} S A x_n = 0.$$

As $A$ is injective, $y_0 = 0$ and $\pi(S)$ is closed.

Thus $\pi$ is a linear map of $S$ onto $B(\mathcal{H}')$. Apply the Closed Graph Theorem again. Suppose $\lim S_n = 0$ and $\lim \pi(S_n) = X$ in $B(\mathcal{H}')$. Then
\[ Ay_0 = \lim_{n \to \infty} A \pi(S)x_n = \lim_{n \to \infty} S Ax_n = 0. \]

As \( A \) is injective, \( y_0 = 0 \) and \( \pi(S) \) is closed.

Thus \( \pi \) is a linear map of \( S \) onto \( B(\mathcal{H}') \). Apply the Closed Graph Theorem again. Suppose \( \lim S_n = 0 \) and \( \lim \pi(S_n) = X \) in \( B(\mathcal{H}') \). Then
\[ AX = \lim_{n \to \infty} A \pi(S_n) = \lim_{n \to \infty} S_n A = 0. \]

Again the injectivity of \( A \) implies \( X = 0 \). So \( \pi \) is continuous. \( \blacksquare \)

**Theorem.** Let \( \mathcal{A} \) be an abelian \( C^* \) algebra, and let \( L \) be an invariant operator range for \( \mathcal{A} \). Then there is a positive operator \( A \) in \( \mathcal{A}' \) such that \( L = A \mathcal{H} \).

**Proof.** Let \( L = B \mathcal{H}' \) for some injective operator \( B \). By Lemma 15.25, there is a representation \( \pi \) of \( \mathcal{A} \) in \( B(\mathcal{H}') \) so that \( SB = B \pi(S) \) for all \( S \) in \( \mathcal{A} \). Let \( U \) be the unitary group of \( \mathcal{A} \), so \( \pi(U) \) is a bounded abelian group in \( B(\mathcal{H}') \). By Corollary 17.2, there is an operator \( T \) so that \( T \pi(U) T^{-1} \) is unitary for all \( U \) in \( U \). Let \( B_0 = BT^{-1} \) and \( \pi_0(S) = T \pi(S) T^{-1} \). Then \( \mathcal{R}(B_0) = T \mathcal{R}(B) = L \) and \( \pi_0 \) is a \( * \)-representation satisfying
\[ SB_0 = SB T^{-1} = B \pi(S) T^{-1} = B_0 \pi_0(S). \]

The polar decomposition of \( B_0^* \) yields the factorization \( B_0 = AU \) where \( A = (B_0 B_0^*)^{1/2} \) is a positive operator in \( B(\mathcal{H}) \) and \( U \) is an isometry (since \( B_0 \) is injective) of \( \mathcal{H}' \) onto \( \mathcal{L} \). Let \( \pi_1(S) = U \pi_0(S) U^* \) be a \( * \)-representation of \( \mathcal{A} \) into \( B(\mathcal{H}) \). Then for all \( S \) in \( \mathcal{A} \),
\[ SAU = AU \pi_0(S) = A \pi_1(S) U. \]

Since \( U \) is an isometry onto \( \mathcal{L} = (\ker A)^\perp \supseteq (\ker \pi_1(S))^\perp \), \( SA = A \pi_1(S) \).

Now \( S^*A = A \pi_1(S^*) = A \pi_1(S)^* \), so
\[ SA^2 = A \pi_1(S) A = A(A \pi_1(S)^*)^* = A(S^*A)^* = A^2 S. \]

So \( A^2 \), and hence \( A \), belongs to \( \mathcal{A}' \). \( \blacksquare \)

Now we are in a position to compute the invariant operator ranges of algebras with commutative subspace lattices (CSL’s). (See Chapter 22 for detailed information about this class.)

**Lemma.** Let \( \mathcal{H} = \sum_{n \geq 1} \mathcal{H}_n \) and let \( T_{ij} \) be operators in \( B(\mathcal{H}_j, \mathcal{H}_i) \).

Suppose \( B = (b_{ij}) \) is a bounded operator on \( \ell_2 \) such that \( \| T_{ij} \| \leq b_{ij} \) for every \( i,j \geq 1 \). Then the matrix \( T = (T_{ij}) \) represents a bounded operator from \( \mathcal{H} \) to itself with \( \| T \| \leq \| B \| \).
Proof. Let \( x = (x_k) \) be a unit vector in \( \mathcal{H} \). Then \( u_i = \|x_i\| \) determines a unit vector \( u = (u_1, u_2, \ldots) \) in \( \ell_2 \). So

\[
\|T x\|^2 = \sum_{i=1}^{\infty} \left( \sum_{j=1}^{\infty} T_{ij} x_j \right)^2 \leq \sum_{i=1}^{\infty} \left( \sum_{j=1}^{\infty} \|T_{ij}\| \|x_j\| \right)^2 \\
\leq \sum_{i=1}^{\infty} \left( \sum_{j=1}^{\infty} b_{ij} u_j \right)^2 = \|Bu\|^2 \leq \|B\|^2.
\]

\[\Box\]

15.28 Lemma. Let \( \mathcal{T} \) be a norm closed algebra and let \( \mathcal{M} \) be a masa such that \( \mathcal{M} \mathcal{M}^* = \mathcal{T} \). Suppose \( A \) is a positive contraction in \( \mathcal{M} \) and \( L = \mathcal{R}(A) \) is invariant for \( \mathcal{T} \). Set \( E_n = E_A(2^{-n}, 1) \) and let \( L_n = \overline{\mathcal{R}_{n} \mathcal{H}} \). There is an integer \( k \) so that \( \mathcal{P}(L_{n}) \leq E_{n+k} \) for all \( n \geq 1 \).

Proof. If the lemma is false, it is due to one of three possibilities:

Case 1. There exists an \( n_0 \) such that \( E_A(0)L_{n_0} \neq 0 \).

Case 2. There exists an \( n_0 \) so that \( E_k L_{n_0} \neq 0 \) for all \( n \geq 0 \).

Case 3. There is a sequence \( n_1 < n_2 < \ldots \) such that \( E_{n_{k+3k}} L_{n_k} \neq 0 \) for \( k \geq 1 \).

Exclude from Cases 2 and 3 any situation handled by the previous case.

Case 1. Since \( \mathcal{R}_{n_0} \mathcal{H} \) is dense in \( L_{n_0} \), there is an operator \( T \) in \( \mathcal{T} \) so that \( E_A(0) \mathcal{R}_{n_0} \mathcal{H} \neq 0 \). But \( E_A(0)A = 0 \) while \( E_{n_0} \mathcal{H} \) is contained in \( \mathcal{R}(A) \). Thus \( \mathcal{R}(A) \) is not invariant for \( \mathcal{T} \), contrary to hypothesis.

Case 2. As case 1 is excluded, \( \mathcal{R}_{n_0} \mathcal{H} = E_A(0)^{\perp} \mathcal{R}_{n_0} \mathcal{H} \). Since \( E_A(0)^{\perp} = \text{sup}E_n \), one can extract a subsequence \( n_0 \leq n_1 < n_2 < \ldots \) so that \( n_k \geq 4k \) and \( P_k = E_{n_k+1} - E_{n_k} \) satisfies \( P_k \mathcal{R}_{n_0} \mathcal{H} \neq 0 \). Choose \( T_k = P_k T_k E_{n_0} \) in \( \mathcal{T} \) of norm one (possible since \( \mathcal{M} \mathcal{M}^* = \mathcal{T} \)), and set \( T = \sum_{k=1}^{\infty} 2^{-k} T_k \). Choose unit vectors \( y_k \) in \( E_{n_0} \mathcal{H} \) so that \( \|T_k y_k\| > 1 \).

Inductively define \( \epsilon_k = 0 \) or 1, and \( w_k = \sum_{j=1}^{k} \epsilon_j 2^{-j} y_j \) as follows: if \( \|T_k w_{k-1}\| < 4^{-k}/2 \), set \( \epsilon_k = 1 \); otherwise set \( \epsilon_k = 0 \). Let \( y = \sum_{k=1}^{\infty} \epsilon_k 2^{-k} y_k \).

Then

\[
\|P_k T y\| = \|2^{-k} T_k y\| \geq 2^{-k} \|T_k w_{k-1}\| - \epsilon_k 2^{-k} \|T_k y_k\| - 2^{-k} \sum_{j>k} 4^{-j} \\
\geq 2^{-k} \cdot 3^{n_k} - 2^{-k} \cdot 9^{n_k}/3 = 8^{-k}/15.
\]

Now \( y = E_{n_0} y \) belongs to \( \mathcal{R}(A) \). However \( \|A^{-1} P_k y\| \leq 2^{-n_k} \leq 2^{-k} \), so \( \|A^{-1} P_k T y\| \geq 2^{-k}/15 \). It follows that \( Ty \) is not in \( \mathcal{R}(A) \). This contradicts
the invariance of \( L \), and so rules out case 2.

**Case 3.** As case 2 is ruled out, for each \( n_k \) there is an integer \( m_k \) so that \( E_{m_k} E_{n_k} = 0 \). Drop to a subsequence (also labelled \( n_k \) for convenience) so that \( n_{k+1} > m_k \). Let \( P_k = E_{n_k} - E_{n_{k-1}} \) and \( Q_k = E_{m_k} - E_{n_{k+3}} \). Then \( Q_k P_k \neq 0 \) but \( Q_k E_{n_{k-1}} = 0 \). Choose operators \( T_k = Q_k T_k P_k \) of norm one in \( T \), and choose unit vectors \( y_k = P_k y_k \) so that \( \|T_k y_k\| > \frac{1}{2} \).

Set \( T = \sum_{k=1}^{\infty} 2^{-k} T_k \). Now \( AP_k \geq 2^{-n_k} P_k \) so there is a (unique) vector \( z_k = P_k z_k \) such that \( Az_k = y_k \); and \( \|z_k\| \leq 2^{n_k} \). Set \( z = \sum_{k=1}^{\infty} 2^{-n_k} z_k \).

Then \( y \equiv Az = \sum_{k=1}^{\infty} 2^{-n_k} y_k \) belongs to \( \mathcal{R}(A) \). But

\[
Ty = \sum_{k=1}^{\infty} 2^{-n_k-n_{k+3}} T_k y_k = \sum_{k=1}^{\infty} 2^{-n_k-2k} Q_k T_k y_k .
\]

Now \( \|AQ_k\| \leq 2^{-n_k-n_{k+3}} \), so \( \|A^{-1} Q_k T y\| \geq 2^k \|T_k y_k\| > 2^{k-1} \). Consequently, \( Ty \) is not in \( \mathcal{R}(A) \). This again is a contradiction, so the lemma is established.

**15.29 Theorem.** Let \( T \) be a norm closed algebra such that \((T \cap T^\prime)^\prime\) contains a masa \( M \) and \( M^2 M = T \). Let \( L = \text{Lat} T \). Then the following are equivalent:

1. \( L \) is an invariant operator range for \( T \).
2. \( L \) is an invariant operator range for \( \text{Alg} L \).
3. \( L = A \mathcal{K} \) where \( A = \sum_{n \geq 1} 2^{-n} P(L_n) \) where \( \{L_n \mid n \geq 1\} \) is an increasing sequence of elements of \( L \).
3'. \( L = A \mathcal{K} \) where \( A \) is on the norm closed convex hull of \( \{P(L) \mid L \in L \} \).
4. \( L = A \mathcal{K} \) where \( A \) is in the weak operator convex hull of \( \{P(L) \mid L \in L \} \).
4'. \( L = A \mathcal{K} \) where \( A \) belongs to \( M_+ \) and the ranges of the spectral projections \( E_{A}(\epsilon, \infty) \) belong to \( L \) for all \( \epsilon \geq 0 \).

**Proof.** Clearly, (3) \( \Rightarrow (3') \Rightarrow (4) \Rightarrow (4') \). If (4') holds, normalize so that \( \|A\| = 1 \). Let \( P_0 = 0 \) and \( P_n = E_{A}(2^{-n}, \infty) \). By hypothesis, there is an increasing sequence \( L_n \) in \( L \) so that \( P_n = P(L_n) \). Let

\[
A_0 = \sum_{n=1}^{\infty} 2^{-n} P_n = \sum_{n=1}^{\infty} 2^{1-n} (P_n - P_{n-1}) = \sum_{n=1}^{\infty} 2^{1-n} E_{A}(2^{-n}, 2^{1-n}) .
\]

Then \( \frac{1}{2} A_0 \leq A \leq A_0 \) hence there is an invertible operator \( M \) in \( \mathcal{M} \) so that \( A_0 = AM \). Thus \( \mathcal{R}(A_0) = \mathcal{R}(A) = L \), whence (4') \( \Rightarrow (3) \).
If (3) holds, set \( Q_n = P(L_n) - P(L_{n-1}) \) for \( n \geq 1 \) and \( L_0 = 0 \). Fix \( T \) in \( \text{Alg} \ L \), and let \( T_{nm} = Q_n T Q_m = (Q_n T Q_m)' \). Since \( T Q_m = P(L_m) T Q_m \), \( T_{nm} = 0 \) for \( n > m \). Now \( A Q_m = 2^{1-n} Q_m \), thus \( A^{-1} T_{nm} A^n = 2^{n-m} T_{nm} \).

Set \( b_{nm} = 0 \) for \( n > m \) and \( b_{nm} = 2^{n-m} ||T|| \) if \( n \leq m \). Then \( B = (b_{nm}) \) is a bounded operator on \( \ell_2 \) with \( \| B \| \leq \sum_{k \geq 0} 2^{k} ||T|| = 2 ||T|| \). By Lemma 15.27, the operator \( S \) on \( H = \bigoplus_{n=1}^{\infty} Q_n H \) with matrix \( (2^{n-m} T_{nm}) \) is bounded. Moreover \( A \) has the diagonal matrix form \( \text{diag}(2^{1-n} Q_n) \), so \( AS \) and \( TA \) both have the matrix form \( (2^{1-n} T_{nm}) \). Thus \( TA = AS \) and consequently \( R(A) \) is invariant for \( T \). So (3) implies (2). Clearly (2) implies (1).

Suppose (1) holds. Then \( L \) is invariant for \( T \cap T \). Hence by Theorem 15.26, there is a positive operator \( A \) in \( (T \cap T)' \) so that \( L = A H \). Since \( (T \cap T)' \) contains \( M \), \( (T \cap T)' = (T \cap T)' \) is contained in \( M \). Normalize \( A \) so that \( ||A|| = 1 \), and let \( E_n = E(2^{-n}, 1) \). Let \( L = TE_n H \) be the smallest subspace in \( \text{Lat} T \) containing \( R(E_n) \). By Lemma 15.28, there is an integer \( k \) so that \( P(L_n) \leq E_{n+k} \) for all \( n \geq 1 \). Once this is established, set

\[
A_0 = \sum_{n=1}^{\infty} 2^{-n} P(L_n) \leq \sum_{n=1}^{\infty} 2^{-n} E_{n+k} \leq 2^k A
\]

Then \( 2^{-k} A_0 \leq A \leq A_0 \). Hence there is an invertible operator \( M \) in \( M \) so that \( A_0 = A M \). Thus \( L = R(A) = R(A_0) \) and (1) implies (3).

**15.30 Corollary.** Let \( H \) be a nest such that \( H^* \) is well ordered. Then the only invariant operator ranges of \( T \) (\( H \)) are the elements of \( H \) itself.

**Proof.** Let \( L \) be an invariant operator range of \( T \) (\( H \)). By Theorem 15.29, there is an increasing sequence \( N_k \) in \( H \) so that \( L = A H \) where \( A = \sum_{k \geq 1} 2^{-k} P(N_k) \). But the sequence \( N_k \) is eventually constant by the well ordering hypothesis, say \( N_k = N_{k_0} \) for \( k \geq k_0 \). Then \( 2^{-k_0} P(N_{k_0}) \leq A \leq P(N_{k_0}) \) and thus \( L = N_{k_0} \).

**Remark.** The condition \( (T \cap T)' \) is essential. Let \( T_0 \) be the algebra of strictly upper triangular operators with respect to a basis \( \{e_n, n \geq 1\} \). This algebra has invariant operator ranges which are not the range of a diagonal operator. The proof of Theorem 15.29 shows however that every range of a diagonal operator invariant for \( T_0 \) is also invariant for \( T = \text{Alg} \text{Lat} T_0 \).
Notes and Remarks.

A deeper treatment of tensor products can be found in $C^*$-algebra texts such as Kadison-Ringrose, [3] vol. 2 or Takesaki [2]. The notion of reflexivity for subspaces is due to Loginov and Sul'man [1]. The duality argument, Lemma 15.4, and Theorems 15.9 and 15.11 and their corollaries are due to Arveson [6]. The treatment given here is new. Radjavi and Rosenthal [1] proved Corollary 15.12 for the weak operator topology. Theorem 15.14 is due to Erdos and Power [1]. Theorem 15.15 is somewhat new, but the ideas are mostly contained in Power [9] who proves Corollary 15.16. Longstaff [1] proved Corollary 15.17. Theorem 15.19 was proved for a special nest by Arveson [7]. The proof in full generality is basically the same. Operator ranges were introduced by Foias [1] who proved most of the results of the last section. The proof of Lemma 15.20 is taken from Filmore and Williams [1]. Lemma 15.27 is due to Nordgren, Radjali-pour, Radjavi and Rosenthal [1]. Lemma 15.19 and Theorem 15.29 are due to Davidson [3], but the main ideas are already in Foias’s paper. Davidson [3] contains the example referred to in Remark 15.31 (See Exercise 15.11). Ong [1, 2] has some related results.

Exercises.

15.1 Show that there is a constant $C$ so that

$$\text{dist}(T, \mathcal{A} \otimes I) \leq C \sup_{P \in \text{lat} \mathcal{A} \otimes I} ||P^{1/2}TP||$$

for every $T$ in $B(\mathcal{H}_1 \otimes \mathcal{H})$ and every weak* closed subalgebra of $B(\mathcal{H}_1)$.

15.2* Prove Lemma 15.7 without measure theory.

15.3 One has to go to certain extra trouble in Lemmas 15.5 and 15.7 due to the fact that the positive operators do not form a lattice. The following exercises are to emphasize this fact.

(a) Show that a $2 \times 2$ Hermitian matrix $A$ is positive if and only if $tr A \geq 0$ and $det A \geq 0$.

(b) Let $A = \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$ and $B = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$. Find two (or all) positive operators $P$ which are greater than both $A$ and $B$ and are minimal with this property.

(c) Show that the self-adjoint elements in an abelian von Neumann algebra do form a complete lattice.

(d) Let $X = \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix}$. Find two (or all) positive, diagonal operators $D \geq X$ which are minimal with this property.
15.4 (Rosenthal) Show that the algebra $\mathcal{A}$ consisting of all operators on $\mathcal{H} \oplus \mathcal{K}$ of the form $\begin{bmatrix} \alpha I & T \\ 0 & \beta I \end{bmatrix}$ where $T$ belongs to $\mathcal{B}(\mathcal{H})$ and $\alpha, \beta$ are scalars is a reflexive algebra which is not finitely generated.

15.5 (Erdos-Power) Let $S = S_\Phi$ be a weak* closed $\mathcal{T}(\mathcal{H})$ bimodule.
   (a) Show that $S$ is an ideal if and only if $\Phi(N) \leq N$ for all $N$ in $\mathcal{H}$.
   (b) Show that $S$ is an algebra if and only if $\Phi(\Phi(N)) \leq \Phi(N)$ for all $N$ in $\mathcal{H}$.

15.6 (Erdos-Power) Show that $S_\Phi$ is the second dual of $S_\Phi \cap \mathcal{K}$.

15.7 (Erdos-Power) Prove that $S_\Phi + \mathcal{K}$ is norm closed.

15.8* (Power) Does every nest have the property: if $A_t$ belong to $\mathcal{T}(\mathcal{H})$ and $\sum_{i=1}^{n} A_t^* A_t = P$ is invertible, then there is an operator $C$ in $\mathcal{T}(\mathcal{H})^{-1}$ such that $C^* C = P$.

15.9 (Arveson)
   (a) Use Theorem 8.9 to construct an expectation of $\mathcal{B}(\mathcal{H}^2)$ onto the set of Toeplitz operators, and takes operators in $\mathcal{T}(\mathcal{P})$ to co-analytic Toeplitz operators where $\mathcal{P} = \{P_n = \text{span} \{1, z, \ldots, z^n\}, n \geq 0\}$.
   (b) If $f_1, \ldots, f_n$ belong to $H^\infty$ and $\sum_{i=1}^{n} \|T_{f_i}^* x\|^2 \geq \varepsilon^2 \|x\|^2$ for all $x$ in $H^2$, prove that there exist $g_1, \ldots, g_n$ in $H^\infty$ so that $\sum_{i=1}^{n} g_i f_i = 1$.

15.10 Let $\mathcal{T}_0$ denote the strictly lower triangular operators with respect to a basis $\{e_n, n \geq 1\}$. Find all invariant operator ranges of $\mathcal{T}_0$.

15.11 (Davidson) Let $\mathcal{T}_0$ be the strictly upper triangular operators with respect to a basis $\{e_n, n \geq 1\}$. Let $\{f_n, g_n, n \geq 1\}$ be a basis for a Hilbert space $\mathcal{H}$, and set $x_n = f_n + 2^{-k/2} g_k$ for $2^{k-1} \leq n < 2^k$, $k \geq 1$. Let $\mathcal{X} = \text{span} \{x_n, n \geq 1\}$. Define $A$ in $B(\mathcal{X}, \mathcal{H})$ by $Ax_n = 2^{-n^2} e_n$ and extend linearly. For each $T$ in $\mathcal{T}_0$ with matrix $(t_{ij})$, define $\pi(T)$ in $B(\mathcal{X})$ by $\pi(T)x_n = \sum_{i=1}^{n-1} 2^{i-n} t_{in} x_i$.
   (a) Prove that $\pi$ is continuous and $TA = A\pi(T)$ for all $T$ in $\mathcal{T}_0$. Hence $R(A)$ is invariant for $\mathcal{T}_0$.
   (b) Prove that $\pi$ does not extend to $\mathcal{T}$, and hence $R(A)$ is not invariant for $\mathcal{T}$. 
16. Duality

In this chapter, we show that any nest algebra is the second dual of $T(\mathcal{N}) \cap K$. Knowledge of the extreme points of the pre-annihilator of $T(\mathcal{N})$ will yield new proofs of the Arveson Distance Formula and the Erdos Density Theorem. Because we wish to obtain these results as corollaries, we must avoid their use in the development used here. The reader will probably recognize a number of short cuts based on the material developed back in Chapter 3. (We will use the easy Lemma 3.7.) In the last half of this chapter, we investigate the decomposition of trace class operators in $T(\mathcal{N})$ into sums of rank one operators.

Let

$$\mathcal{A} = T(\mathcal{N})_{\perp} = \{ A \in \mathcal{C}_1 : tr(TA) = 0 \text{ for all } T \text{ in } T(\mathcal{N}) \},$$

and let

$$\mathcal{A}_0 = \{ A \in \mathcal{C}_1 : \Delta(A) = 0 \}$$

$$= \{ A \in \mathcal{C}_1 : P(N) - \frac{1}{2} AP(N) = 0 \text{ for all } N \in \mathcal{N} \}. $$

Also let $\mathcal{R} = T(\mathcal{N}) \cap K$ and let $\mathcal{R}_0$ be the norm closed span of the rank one operators in $\mathcal{R}$. (By Corollary 3.12, we know that $\mathcal{R}_0 = \mathcal{R}$.) The first step will be to compute the extreme points of $\mathcal{A}_0$. To do this, we need a decomposition argument based on the $2 \times 2$ matrix results Lemma 14.13 and Corollary 14.14.

16.1 Lemma. Let $T = \begin{bmatrix} T_{11} & T_{12} \\ 0 & T_{22} \end{bmatrix}$ represent a trace class operator from $\mathcal{H}_1 \oplus \mathcal{H}_2$ to $\mathcal{K}_1 \oplus \mathcal{K}_2$. Then there is a decomposition $T = T_1 + T_2$ such that $T_1 = \begin{bmatrix} T_{11} & Y_1 \\ 0 & 0 \end{bmatrix}$, $T_2 = \begin{bmatrix} 0 & Y_2 \\ 0 & T_{22} \end{bmatrix}$, and $\|T\|_1 = \|T_1\|_1 + \|T_2\|_1$.

Proof. Let $T = UQ$ be the polar decomposition of $T$. Write $Q = \begin{bmatrix} A & B \\ B^* & D \end{bmatrix}$ and apply Lemma 14.13. There is a bounded operator $X$ from $\mathcal{H}_2$ to $\mathcal{H}_1$ so that $B = A^*X$. Also, $Q_1 = \begin{bmatrix} A & B \\ B^* & X^*X \end{bmatrix}$ is positive and less than $Q$; where $Q_2 = \begin{bmatrix} 0 & 0 \\ 0 & D - X^*X \end{bmatrix}$ is positive. Since $Q$ is trace class, so are $Q_1$ and $Q_2$ and
\[
\|Q\|_1 = \text{tr}Q = \text{tr}Q_1 + \text{tr}Q_2 = \|Q_1\|_1 + \|Q_2\|_1.
\]

Let \( U = [U_{ij}] \), and define \( T_1 = UQ_1 \) and \( T_2 = UQ_2 \). Clearly, \( T_2 \) has the form
\[
\begin{bmatrix}
0 & * \\
0 & *
\end{bmatrix},
\]
so \( T_1 \) has the form
\[
\begin{bmatrix}
T_{11} & Y_1 \\
0 & U_{21}B + U_{22}X^*X
\end{bmatrix}.
\]
Since \( UQ = T \) is triangular, Corollary 14.14 yields the identity \( U_{21}A^* + U_{22}X^* = 0 \). So
\[
T_1 = UQ_1 = \begin{bmatrix} T_{11} & Y_1 \\ 0 & U_{21}B + U_{22}X^*X \end{bmatrix}
= \begin{bmatrix} T_{11} & Y_1 \\ 0 & (U_{21}A^* + U_{22}X^*)X \end{bmatrix} = \begin{bmatrix} T_{11} & Y_1 \\ 0 & 0 \end{bmatrix}.
\]
Thus \( T_2 = T - T_1 = \begin{bmatrix} 0 & Y_2 \\ 0 & T_{22} \end{bmatrix} \) where \( Y_2 = T_{12} - Y_1 \). Finally,
\[
\|T\|_1 = \|Q\|_1 = \|Q_1\|_1 + \|Q_2\|_1 \geq \|T_1\|_1 + \|T_2\|_1 \geq \|T\|_1.
\]
So equality follows.

16.2 Lemma. \( A_0 \) is the annihilator of \( R_0 \). The extreme points of \( b_1(A_0) \) are the rank one operators \( x \otimes y^* \) where \( \|x\| = \|y\| = 1 \), and for some \( N \) in \( \mathcal{H} \), \( x \in N \) and \( y \in N^\perp \).

Proof. By Lemma 3.7, \( R_0 \) is spanned by \( u \otimes v^* \) where \( u \in N \) and \( v \in N^\perp \) for some \( N \) in \( \mathcal{H} \). Thus the annihilator of \( R_0 \) consists of all trace class operators \( A \) such that
\[
0 = \text{tr}(Au \otimes v^*) = (Au, v)
\]
for all such \( u \) and \( v \). Hence \( AN \) is orthogonal to \( (N_\perp)^\perp \). That is, \( P(N_\perp)^\perp AP(N) = 0 \) for all \( N \) in \( \mathcal{H} \). Conversely, if this holds, \( A \) annihilates each rank one operator in \( R_0 \). This condition characterizes \( A_0 \), so \( A_0 = R_0^\perp \).

Let \( A \) be an extreme point of \( b_1(A_0) \). Let \( N \) belong to \( \mathcal{H} \). Since \( \Delta(A) = 0 \), \( A \) maps \( N \) into \( N_\perp \). So as an operator from \( \mathcal{H} = N \oplus N^\perp \) to \( \mathcal{H} = N_\perp \oplus N^\perp \), \( A \) has the form
\[
A = \begin{bmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{bmatrix}.
\]
If \( A_{11} \) and \( A_{22} \) are both non-zero, Lemma 16.1 decomposes \( A = A_1 + A_2 \) so that
\[
\|A\|_1 = \|A_1\|_1 + \|A_2\|_1 \text{ and } A_1 = \begin{bmatrix} A_{11} & Y_1 \\ 0 & 0 \end{bmatrix} \text{ and } A_2 = \begin{bmatrix} 0 & Y_2 \\ 0 & A_{22} \end{bmatrix}.
\]
Both \( A_i \) are non-zero. Since \( A_1 \) and \( A_2 \) belong to \( T(N) \) and \( \Delta(A) = \Delta(A_1) \oplus \Delta(A_2) = 0 \), it follows that both \( A_1 \) and \( A_2 \) belong to \( A_0 \). Hence
\[
A = \|A_1\|_1(\|A_1\|^{-1}A_1) + \|A_2\|_1(\|A_2\|^{-1}A_2)
\]
is not an extreme point. Consequently, for each \( N \) in \( \mathcal{H} \), either
Let $N$ be the greatest element of $\mathcal{N}$ such that $A = AP(N)^\perp$. For $N > N$, $A = P(N)A$. Take the infimum over all $N > N$, and since $(N_+) - \leq N$, one obtains $A = P(N)AP(N)^\perp$. Now $P(N)B(N)P(N)^\perp$ is contained in $A_0$. By section 1.2, $A = \sum_{n \geq 1} s_n e_n \otimes f_n^*$ where $s_n$ are the $s$-numbers of $A$ and $\|e_n\| = \|f_n\| = 1$. Since $\sum_{n \geq 1} s_n = \|A\|_1 = 1$, $e_n \in N$, and $f_n \in N^\perp$, $A$ is the convex combination of elements $e_n \otimes f_n^*$ in $b_1(A_0)$. As $A$ is extreme, $s_1 = 1$ and $s_n = 0$ for $n \geq 2$. That is, $A$ is rank one of the desired form.

10.3 Lemma. Let $T = \begin{bmatrix} T_1 & T_2 \\ T_3 & T_4 \end{bmatrix}$ be a trace class operator from one space to another. Suppose $\|T\|_1 \leq 1$ and $\|T_i\|_1 \geq 1 - \epsilon$ for $0 \leq \epsilon \leq 1$. Then $\|\begin{bmatrix} T_1 & T_2 \\ T_3 & T_4 \end{bmatrix}\|_1 \leq 4\epsilon^4$.

Proof. Let $A_i, 1 \leq i \leq 4$, be norm one operators such that $tr(T_i A_i) = \|T_i\|_1$. Then

$$1 \geq tr(T \begin{bmatrix} A_1 & 0 \\ 0 & A_4 \end{bmatrix}) = tr(T_1 A_1) + tr(T_1 A_4)$$

$$= \|T_1\|_1 + \|T_4\|_1.$$

Hence $\|T_4\|_1 \leq \epsilon$. Also if $c$ and $s$ are positive reals with $c^2 + s^2 = 1$,

$$1 \geq tr(T \begin{bmatrix} cA_1 & 0 \\ sA_2 & 0 \end{bmatrix}) = c tr(T_1 A_1) + s tr(T_2 A_2)$$

$$= c \|T_1\|_1 + s \|T_2\|_1.$$

Maximizing over all choices of $c$ yields $\|T_1\|^2 + \|T_2\|^2 \leq 1$, so $\|T_2\|_1 \leq (2\epsilon)^4$. Likewise, $\|T_3\|_1 \leq (2\epsilon)^4$. So

$$\|\begin{bmatrix} T_1 & T_2 \\ T_3 & T_4 \end{bmatrix}\|_1 \leq \|T_2\|_1 + \|T_3\|_1 + \|T_4\|_1$$

$$\leq (2\sqrt{2} + 1)\epsilon^4 \leq 4\epsilon^4.$$

10.4 Corollary. Suppose that $\|T_n\|_1 \leq 1$ for $n \geq 1$, $\|T\|_1 = 1$ and $T_n$ converge weak* to $T$ (i.e. in the $\tau(C_1,K)$ topology). Then $T_n \rightharpoonup T$ in norm.

Proof. Let $T = \sum_{i \geq 1} s_i e_i \otimes f_i^*$ and let $P_k$ and $Q_k$ be the projections onto $span\{e_1,\ldots,e_k\}$ and $span\{f_1,\ldots,f_k\}$ respectively. Then $P_k T Q_k$ converges to
\[ T \text{ in the trace norm, and } \| T - P_k T Q_k \|_1 = 1 - \| P_k T Q_k \|_1. \] Given \( \varepsilon > 0 \), choose \( k \) so large that \( \| P_k T Q_k \| > 1 - \varepsilon \). Now \( P_k T_n Q_k \) converges weak* to \( P_k T Q_k \) (for fixed \( k \)). Since \( P_k C_k Q_k \) is finite dimensional, \( P_k T_n Q_k \) converges to \( P_k T Q_k \) in norm. Choose \( n_0 \) so large that for all \( n \geq n_0 \), \( \| P_k (T - T_n) Q_k \|_1 < \varepsilon \) and \( \| P_k T_n Q_k \|_1 > 1 - \varepsilon \). By Lemma 16.3, \( \| T_n - P_k T_n Q_k \|_1 < 4 \varepsilon \). So
\[
    \| T - T_n \|_1 \leq \| P_k (T - T_n) Q_k \| + \| T - P_k T Q_k \| + \| T_n - P_k T_n Q_k \|
    < \varepsilon + \varepsilon + 4 \varepsilon \varepsilon.
\]
Hence \( T_n \) converges to \( T \) in norm.

16.5 Corollary. The ball \( b_1(A_0) \) is the norm closed convex hull of its extreme points.

Proof. By Lemma 16.2, \( A_0 \) is the annihilator of \( R_0 \), and thus is a dual space (of \( K/R_0 \)). So by the Krein-Milman Theorem, \( b_1(A_0) \) is the weak* closed convex hull of its extreme points. By Corollary 16.4, the boundary of \( b_1(A_0) \) is in the norm closure of the convex hull. The result follows.

16.6 Theorem. \( A_0 = \{ A \in C_1 \cap \mathcal{T}(N): \Delta(A) = 0 \} \) is the pre-annihilator of \( \mathcal{T}(N) \) and the annihilator of \( \mathcal{T}(N) \cap K \). Thus \( \mathcal{T}(N) \) is the second dual of \( \mathcal{T}(N) \cap K \).

Proof. By Corollary 16.5, an operator \( T \) annihilates \( A_0 \) if and only if it annihilates each extreme point. By Lemma 16.2, this holds exactly when \( 0 = (T x, y) \) for every \( x \in N \), \( y \in N^\perp \), \( N \in \mathcal{H} \). That is, precisely when \( T \) belongs to \( \mathcal{T}(N) \). By the Hahn-Banach Theorem, \( A_0 \) is the pre-annihilator of \( \mathcal{T}(N) \). The pre-annihilator of \( A_0 \) is \( R_0 \), and this necessarily includes \( \mathcal{T}(N) \cap K \). Since the reverse inclusion is trivial, \( R_0 = \mathcal{T}(N) \cap K \). The dual of \( \mathcal{T}(N) \cap K \) is \( C_1/A_0 \) and the dual of \( C_1/A_0 \) is \( A_0^\perp = \mathcal{T}(N) \).

16.7 Corollary. (Erdos Density Theorem) The finite rank operators in \( b_1(\mathcal{T}(N)) \) are norm dense in \( b_1(\mathcal{T}(N) \cap K) \) and weak* dense in \( b_1(\mathcal{T}(N)) \).

Proof. \( \mathcal{T}(N) \cap K = R_0 \) is the closed span of the rank one operators. By Goldstines' Theorem, the unit ball of any Banach space is weak* dense in the ball of its second dual.

16.8 Corollary. (Arveson's Distance Formula) If \( \mathcal{H} \) is a nest and \( A \) is an operator, then
\[
\text{dist}(A, \mathcal{T}(N)) = \sup_{N} \| P(N)^\perp A P(N) \|.
\]

Proof. As \( \mathcal{T}(N) \) is weak* closed, a standard separation theorem yields
\[ \text{dist}(A, T(N)) = \sup_{T \in T(N), \|T\|_1 = 1} |\text{tr} AT| \]
\[ = \sup_{\|x\| = \|y\| = 1} \{(Ax, y) : x \in N, y \in N, T(x) = T(y)\} \]
\[ = \sup_P \|P(N)AP(N)\| \] .

\section*{16.9 Corollary. (Lidskii's Theorem)} Let \( T \) be a trace class operator. Then \( \text{tr} T \) equals the sum of its eigenvalues counting algebraic multiplicity.

\textbf{Proof.} First, suppose \( T \) is quasinilpotent. By Corollary 3.2, there is a maximal nest \( \mathcal{N} \) such that \( T \) belongs to \( T(\mathcal{N}) \). Let \( E = P(N) - P(N) \) be an atom of \( \mathcal{N} \), and let \( E = \alpha(E)E \). For \( \lambda \neq 0 \), \( \lambda I - T \) is invertible in \( T(\mathcal{N}) \) since \( (\lambda I - T)^{-1} = \lambda^{-1} \sum_{n \geq 0} \lambda^{-1} T^n \). So
\[ E = E(\lambda I - T)(\lambda I - T)^{-1} \]
\[ = E(\lambda I - T)E(\lambda I - T)^{-1} \]
\[ = (\lambda - \alpha(E))E(\lambda I - T)^{-1} \]
Thus \( \alpha(E) = 0 \) for every \( E \). So \( T \) belongs to \( T(\mathcal{N}) \) and since \( I \in T(\mathcal{N}) \),
\[ \text{tr} T = \text{tr}(IT) = 0 \] .

In general, the Riesz theory shows that the non-zero spectral values of \( T \) are eigenvalues \( \lambda_i \) of finite multiplicity \( n_i \). The eigenvalues correspond to eigenspaces \( E_T(\lambda_i) \) of \( \ker(T - \lambda_i n_i) \). One can choose a basis for \( E_T(\lambda_i) \) so that \( T|E_T(\lambda_i) \) is upper triangular with \( \lambda_i \) on the diagonal. Applying the Gram-Schmidt process to the union yields a basis for \( \mathcal{H}_0 = E_T(\mathcal{N}\setminus\{0\}) \) such that \( T \) is triangular, and each \( \lambda_i \) occurs on the diagonal exactly \( n_i \) times. The compression \( T_0 \) of \( T \) to \( \mathcal{H}_0 \) is quasinilpotent. So
\[ \text{tr} T = \sum_{k \geq 1} \langle \lambda_i \rangle T_0 + \text{tr} T_0 = \sum_{k \geq 1} \langle \lambda_i \rangle T_0 . \]

\section*{16.10 Corollary.} Let \( T \) belong to \( T(\mathcal{N}) \). Then given \( \epsilon > 0 \), there are rank one operators \( R_n \) in \( T(\mathcal{N}) \) such that \( T = \sum \langle n \rangle R_n \) and
\[ \sum_{n \geq 1} \|R_n\|_1 \leq \|T\|_1 + \epsilon . \]

Corollary 16.10 is a simple result, and it is left as an exercise. However, it raises the question of when an exact decomposition into rank one operators is possible. That is, when can one write \( T = \sum \langle n \rangle R_n \) as a sum of
rank one operators in \( \mathcal{T}(\mathcal{H})_\perp \) such that
\[
\|T\|_1 = \sum_{n \geq 1} \|R_n\|_1.
\]
It happens that this *exact decomposition* is always possible precisely when the nest is countable. In general, an integral version is needed. Our analysis is based on a careful examination of the decomposition used in Lemma 16.1.

First, recall from Lemma 16.2 that rank one operators in \( \mathcal{T}(\mathcal{H})_\perp \) are of the form \( R = P(N)RP(N)^\perp \). If a trace class operator has the form 
\( T = P(N)TP(N)^\perp \), then \( T \) belongs to \( \mathcal{T}(\mathcal{H})_\perp \). One can (see Chapter 1) write \( T = \sum_{n \geq 1} s_n R_n \) where \( s_n \geq 0, R_n \) are norm one, rank one operators and \( \sum_{n \geq 1} s_n = \|T\|_1 \). Clearly,
\[
T = \sum_{n \geq 1} s_n P(N)R_n P(N)^\perp,
\]
so \( T \) has an exact decomposition into rank one operators in \( \mathcal{T}(\mathcal{H})_\perp \). So actually, it suffices to decompose an operator into a sum of operators of this type.

**16.11 Proposition.** Let \( T \) be a rank \( n \) operator in \( \mathcal{T}(\mathcal{H})_\perp \). Then there are \( n \) rank one operators \( R_1, \ldots, R_n \) in \( \mathcal{T}(\mathcal{H})_\perp \) such that \( T = \sum_{i=1}^{n} R_i \) and \( \|T\|_1 = \sum_{i=1}^{n} \|R_i\|_1 \).

**Proof.** First we show that the decomposition obtained in Lemma 16.1 has the addition property
\[
rank T = rank T_1 + rank T_2.
\]
Using the notation of that lemma, one has
\[
Q_1 = \begin{bmatrix} I & X^* \\ X & A \end{bmatrix}.
\]
So \( rank Q_1 = rank A \), and \( Ran(Q_1) = \begin{bmatrix} I \\ X^* \end{bmatrix} Ran(A) \) has trivial intersection with \( \mathcal{H}_2 \). But \( Q_2 = \begin{bmatrix} 0 & 0 \\ 0 & D - X^*X \end{bmatrix} \) has range contained in \( \mathcal{H}_2 \). Thus
\[
rank T = rank Q = rank Q_1 + rank Q_2 = rank T_1 + rank T_2.
\]
Now, proceed by induction on \( n \). For \( n = 1 \), it is trivial. Suppose there is a element \( N \) in \( \mathcal{H} \) so that both \( T_{11} = TP(N) \) and \( T_{22} = P(N)^\perp T \) are non-zero. Then the decomposition of Lemma 16.1 with respect to \( \mathcal{H} = N \oplus N_\perp \) and \( K = N_\perp \oplus N_\perp^\perp \) yields \( T = T_1 + T_2 \) where
\[ T_1 = \begin{bmatrix} T_{11} & * \\ 0 & 0 \end{bmatrix} \quad \text{and} \quad T_2 = \begin{bmatrix} 0 & * \\ 0 & T_{22} \end{bmatrix} \] are both non-zero, and hence have rank at least one. By the previous paragraph, the rank of \( T_1 \) and \( T_2 \) is strictly less than \( n \). So by the induction hypothesis, each can be written as an exact sum of rank \( T_i \) rank-one operators. Adding yields the decomposition for \( T \). Otherwise, let \( N \) be the sup of all \( N' \) in \( \mathcal{H} \) such that \( T P(N') = 0 \). Clearly, \( T P(N) = 0 \). Also, if \( N' > N \), then \( T P(N') \neq 0 \) so \( P(N')^{-1} T = 0 \). Consequently, \( P(N)^{-1} T = 0 \) (Verify!). So \( T = P(N)^{-1} T P(N) \) decomposes exactly by the method given in the paragraph preceding this proposition. By induction, this decomposition is valid for all finite rank operators in \( T(\mathcal{H}) \).

The next theorem will immediately be subsumed by its sequel. However, it shows somewhat more simply exactly how the decomposition works.

10.12 Theorem. Let \( \mathcal{H} \) be a well ordered nest. Then every trace class operator \( T \) in \( T(\mathcal{H}) \) is exactly decomposable, i.e., \( T = \sum_{n \geq 1} R_n \), \( \| T \|_1 = \sum_{n \geq 1} \| R_n \|_1 \), and \( R_n \) belong to \( T(\mathcal{H}) \).

Proof. We use the results of section 14.13-14.18. Let \( Q = (T^* T)^{1/2} \), and let \( T = U Q \) be the polar decomposition of \( T \). By Lemma 14.18, one associates to each \( N \) in \( \mathcal{H} \) a positive operator \( Q_N \) such that \( Q = \sum_{N \in \mathcal{H}} Q_N \) converges in the strong operator topology. From section 14.15 and Lemma 14.16, one finds that with respect to the decomposition \( N \oplus (N_+ / N) \oplus N_+^\perp \), \( Q_N \) has the form

\[
Q_N = \begin{bmatrix} 0 & 0 & 0 \\ 0 & A & B \\ 0 & B^* & X \end{bmatrix}
\]

where \( X \) is the least positive operator such that \( Q_N \) is positive. Or in other words, using Lemma 14.13, \( Q \) is decomposed into \( Q | 0, N \) + \( Q | N, \mathcal{H} \) and then \( Q | N, \mathcal{H} \) is likewise decomposed as \( Q_N + Q | N_+, \mathcal{H} \). From the proof of Lemma 16.1, one obtains that operators \( T_N = U Q_N \) belong to \( T(\mathcal{H}) \). Moreover, \( T_N P(N) = 0 \) and \( P(N_+) T_N = 0 \). So \( T_N \) belongs to \( P(N_+) B(\mathcal{H}) P(N) \), which is a subspace of \( T(\mathcal{H}) \) by Lemma 2.8. As in the paragraph preceding Proposition 16.11, \( T_N \) can be exactly decomposed as the sum of rank one operators in this subspace. Finally,

\[
\| T \|_1 = \| Q \|_1 = \text{tr} Q = \sum \text{tr} Q_N = \sum \| Q_N \|_1 = \sum \| T_N \|_1
\]

So the desired decomposition is obtained.
16.13 Theorem. Let $\mathcal{N}$ be a countable nest. Then every trace class operator $T$ in $\mathcal{T}(\mathcal{N})$ is exactly decomposable.

Proof. It is necessary to extend the definition of $Q_N$ of the previous proof to all $N$ in $\mathcal{N}$, even when $N = N_+$, in such a way that

$$Q = \sum_{N \in \mathcal{N}} Q_N$$

is still valid. Set $Q_N = s - \lim_{N' \uparrow N} Q(N,N')$, which exists since $Q(N,N')$ is an increasing function of $N'$. For each finite subnest

$$\mathcal{F} = \{0 = F_0 < F_1 < \ldots < F_n = \mathcal{N}\}$$

of $\mathcal{N}$, let $Q_\mathcal{F} = \sum_{j=0}^{n-1} Q_{F_j}$. It will be shown that $s - \lim_{\mathcal{F}} Q_\mathcal{F} = Q$ in the strong operator topology.

First, $Q_{F_1} \leq Q[F_1,F_{i+1})$, so

$$Q_{\mathcal{F}} \leq \sum_{i=0}^{n-1} Q[F_i,F_{i+1}) = Q[0,N) = Q .$$

Also, if $\mathcal{F}_1$ is contained in $\mathcal{F}_2$, then clearly $Q_{\mathcal{F}_1} \leq Q_{\mathcal{F}_2}$. So this is an increasing nest, bounded above by $Q$. Thus it has a limit. The same can be said for the restriction of this sum to those $F$ such that $N \leq F < M$ say. So let $\mathcal{E}$ consist of all intervals $[N,M)$ such that the equality

$$Q[N,M) = \sum_{N \leq F < M} Q_F$$

holds. The collection $\mathcal{E}$ is non-empty since it contains all atoms $[N,N_+]$ and $\mathcal{N}$ is atomic. It is also hereditary in the sense that if $[N',M') \subseteq [N,M)$ and $[N,M)$ belongs to $\mathcal{E}$, so does $[N',M')$. Also, if $[N,M)$ and $[M,L)$ belong to $\mathcal{E}$, so does $[N,L)$ since $Q[N,L) = Q[N,M) + Q[M,L)$ by definition of $Q[\cdot, \cdot)$. Most importantly, suppose $[N_k,M_k)$ belong to $\mathcal{E}$ and $N_{k+1} \leq N_k < M_k \leq M_{k+1}$. Then $[N_0,M_0)$ belongs to $\mathcal{E}$ where $N_0 = \inf N_k$ and $M_0 = \sup M_k$. To see this, first use Lemma 14.17 to obtain

$$Q[N_1,M_0) = s - \lim_{k \to \infty} Q[N_1,M_k)$$

$$= s - \lim_{k \to \infty} \sum_{N_1 \leq F < M_k} Q_F = \sum_{N_1 \leq F < M_0} Q_F .$$

If $N_0 = N_k$ for some $k$, the result follows. Otherwise from the definition of $Q_N$, one has

$$Q_{N_0} = s - \lim_{k \to \infty} Q[N_0,M_0) - Q[N_k,M_0)$$

whence
\[ Q(N_0, M_0) = Q_{N_0} + s - \lim_{k \to \infty} Q(N_k, N_1) + Q(N_1, M_0) \]
\[ = Q_{N_0} + s - \lim_{k \to \infty} \sum_{N_k \leq F < N_0} Q_F = \sum_{N \in \mathcal{M}} Q_N. \]

Now \( \mathcal{N} \) is atomic and for each atom, one can use Zorn’s lemma to obtain a maximal interval in \( \mathcal{E} \) containing that atom. No two maximal intervals can intersect, or even abut like \( [N, M] \) and \( [M, L] \). Thus if there are two or more intervals, then between each two intervals, there must be another. So these maximal intervals form a dense order type. This implies that \( \mathcal{N} \) is uncountable. As \( \mathcal{N} \) is in fact countable, the maximal interval must be all of \([0, \mathcal{N}]\). So \( Q = \sum_{N \in \mathcal{M}} Q_N \) as desired.

The proof is completed as in Theorem 16.12.

\[ \Box \]

16.14 Lemma. Let \( \mathcal{N} \) be a nest. Suppose \( T \) in \( T(\mathcal{N})_\perp \) has an exact decomposition as a sum of rank one operators in \( T(\mathcal{N}) \). Then it has an exact decomposition as a sum of rank one operators in \( T(\mathcal{N})_\perp \).

Proof. Let \( T = \sum_{n \geq 1} R_n \) where \( \|T\|_1 = \sum_{n \geq 1} \|R_n\|_1 \) and \( R_n \) are rank one in \( T(\mathcal{N}) \). Each \( R \) has the form \( R = P(N)R\{P(N_\perp) \} \) for some \( N \) in \( \mathcal{N} \). But if \( E = P(N) - P(N_\perp) \neq 0 \), it may occur that \( ER_n E \neq 0 \) for some \( n \). Let \( T_E \) be the sum of all \( R_n \) such that \( ER_n E \neq 0 \). Then \( T_E = P(N)T_F P(N_\perp) \), and since \( ETE = 0 \), it follows that \( ET_E E = 0 \). So with respect to the decomposition \( N_+ \oplus E \mathcal{N} \oplus N_\perp \), \( T_E \) has the form

\[ T_E = \begin{bmatrix} 0 & * & * \\ 0 & 0 & * \\ 0 & 0 & 0 \end{bmatrix}. \]

Apply Lemma 16.1 to \( T_E \) as an operator from \( N \oplus N_\perp \) to \( N_+ \oplus N_\perp \). This decomposes \( T_E \) as an exact sum \( T_E = T_1 + T_2 \) where \( T_1 = P(N)T_1 P(N_\perp) \) and \( T_2 = P(N)T_2 P(N) \). By the remark preceding Proposition 16.11, both \( T_1 \) and \( T_2 \) have exact decompositions into rank one operators in \( T(\mathcal{N})_\perp \). So \( T_E \) has such a decomposition. This procedure may be carried out for each of the (countably many) atoms for which \( T_E \neq 0 \). The result is an exact decomposition in \( T(\mathcal{N})_\perp \).

16.15 Corollary. Let \( \mathcal{N} \) be a countable nest, and let \( T \) belong to \( T(\mathcal{N})_\perp \). Then \( T \) decomposes as \( T = \sum_{n \geq 1} R_n \) where \( R_n \) are rank one operators in \( T(\mathcal{N})_\perp \), and \( \|T\|_1 = \sum_{n \geq 1} \|R_n\|_1 \).

Next, we develop the appropriate analogue of Theorem 16.13 for arbitrary nests.
16.16 Lemma. Let $\mathcal{N}$ be a nest on a separable space. Let $Q$ be a positive operator, and define $Q[N,M]$ as in 14.15. Then there is an extension $Q(\Delta)$ defined on all Borel subsets of $\mathcal{N}$ with values in the positive operators which is countably additive in the strong operator topology.

Proof. By definition, $Q[N,M]+Q[M,L] = Q[N,L]$, so $Q$ is finitely additive in this restricted sense. Moreover, if $[N,M]$ is the countable disjoint union of $[N_k,M_k]$, then each endpoint $M_k$ equals $N_j$ for some $j$ except when $M_k = M$. Thus the nest generated by $\{N_k,k \geq 1\}$ is precisely $\{0,N_k,k \geq 1,M,\mathcal{N}\}$ which is countable and in fact is well ordered. By Lemma 14.17, $Q[N,M] = \sum_{k \geq 1} Q[N_k,M_k]$. Since $B(\mathcal{N})$ is the dual of $C_1$ (Theorem 1.15), for each $T$ in $C_1$ one can define

$$Q_T[N,M] = \text{tr}(Q[N,M]T)$$

This is a positive valued function on half open intervals which is countably additive when the union is a half open interval. By a theorem of Caratheodory (Royden [1], p. 257), there is a regular Borel measure $\mu_T$ on $\mathcal{N}$ so that $\mu_T[N,M] = Q_T[N,M]$ for all $N,M$ in $\mathcal{N}$.

Clearly, $\|\mu_T\| \leq \|Q\| \|T\|$. Also since

$$\lambda_1\mu_{T_1}[N,M] + \lambda_2\mu_{T_2}[N,M] = \mu_{\lambda_1T_1 + \lambda_2T_2}[N,M]$$

for all $N$ and $M$ in $\mathcal{N}$, it follows that $\mu(T) = \mu_T$ is a continuous linear map of $C_1$ into the space of bounded regular Borel measures on $\mathcal{N}$. For each fixed Borel set $\Delta$, the map $f_\Delta(T) = \mu_\Delta(\Delta)$ is hence a positive linear functional on $C_1$. So there is a positive operator $Q(\Delta)$ so that

$$\mu_\Delta(\Delta) = \text{tr} Q(\Delta)T$$

for every $T$ in $C_1$. Moreover, if $\Delta$ is the disjoint union of Borel sets $\Delta_i$

$$\text{tr} Q(\Delta)T = \mu_\Delta(\Delta) = \sum \mu_\Delta(\Delta_i) = \sum \text{tr} Q(\Delta_i)T$$

(The sum $\sum Q(\Delta_i)$ is a monotone sequence bounded above, and hence converges strongly.) This identity and the Hahn-Banach Theorem forces $Q(\Delta) = \sum Q(\Delta_i)$, so $Q(\cdot)$ is countably additive.

\[\square\]

16.17 Corollary. Suppose that $Q$ is trace class in Lemma 16.16. Then $Q(\cdot)$ is a trace class valued measure which is countably additive in the norm topology. So $\tau(\Delta) = \text{tr} Q(\Delta)$ is a scalar valued measure mutually absolutely continuous to $Q(\cdot)$.

Proof. Since $Q(\Delta) \leq Q$ for every $\Delta$, it must be trace class. (Of course, the theorem could have been proven using the duality $C_1 = K^*$ instead.) Let $\Delta$ be the disjoint union of Borel sets $\Delta_i$. Then

$$Q_n = \sum_{i=1}^n Q(\Delta_i) \leq Q(\Delta)$$

for each $n$, and hence $\|Q_n\|_1 \leq \|Q(\Delta)\|_1$. By
Lemma 16.15, \( Q(\Delta) = \text{s-lim} Q_n \). By Corollary 16.4, \( Q_n \) converges to \( Q(\Delta) \) in norm. Thus \( \tau(\Delta) = \text{tr} Q(\Delta) \) is a countably additive Borel measure on \( \mathcal{M} \). Clearly, \( \tau(\Delta) = 0 \) if and only if \( 0 = \text{tr} Q(\Delta) = \|Q(\Delta)\| \). So \( \tau(\cdot) \) and \( Q(\cdot) \) are mutually absolutely continuous.

Now we need a Radon-Nikodym theorem.

16.18 Theorem. Let \( Q(\cdot) \) be a countably additive, trace class valued Borel measure on a compact metric space \( X \), and let \( \tau(\cdot) = \text{tr} Q(\cdot) \). There is an integrable Borel function \( D(x) \) with values in \( b_1(\mathcal{C})_+ \) such that

\[
Q(\Delta) = \int \Delta D \ d\tau.
\]

Proof. For each \( K \) in \( \mathcal{K} \), the measure \( \mu_K(\Delta) = \text{tr} Q(\Delta)K \) is absolutely continuous with respect to \( \tau \). By the Radon-Nikodym Theorem, there is an essentially unique positive Borel function \( D_K(x) \) so that

\[
\mu_K(\Delta) = \int \Delta D_K \ d\tau
\]

for all Borel sets \( \Delta \). Since

\[
|\int \Delta D_K \ d\tau| = |\text{tr} Q(\Delta)K| \leq \|Q(\Delta)\| \|K\| = \tau(\Delta)\|K\|,
\]

\( |D_K(x)| \leq \|K\| \) a.e.\( \tau \). If \( K_1 \) and \( K_2 \) are both compact, then

\[
\mu_{\lambda_1 K_1 + \lambda_2 K_2}(\Delta) = \lambda_1 \mu_{K_1}(\Delta) + \lambda_2 \mu_{K_2}(\Delta)
\]

\[
= \int \Delta \lambda_1 D_{K_1} + \lambda_2 D_{K_2} \ d\tau = \int \Delta D_{\lambda_1 K_1 + \lambda_2 K_2} \ d\tau.
\]

So \( D_{\lambda_1 K_1 + \lambda_2 K_2} = \lambda_1 D_{K_1} + \lambda_2 D_{K_2} \) almost everywhere \( d\tau \).

Fix a basis \( \varepsilon_1, \varepsilon_2, \ldots \) and let \( K_0 \) be finite linear combinations of \( \varepsilon_i \otimes \varepsilon_i^* \) with coefficients in \( \mathbb{Q}+\text{i}\mathbb{Q} \). As this set is countable, one may delete a set \( N \) of \( \tau \) measure 0 so that the map taking \( K \) to \( D_K \) is linear on \( K_0 \). By the Monotone Convergence Theorem,

\[
\int X \sum_{n \geq 1} D_{\varepsilon_n \otimes \varepsilon_n} \ d\tau = \sum_{n \geq 1} \int X D_{\varepsilon_n \otimes \varepsilon_n} \ d\tau = \sum_{n \geq 1} \langle Q(X)\varepsilon_n, \varepsilon_n \rangle = \text{tr} Q(X).
\]

Hence \( \sum_{n \geq 1} D_{\varepsilon_n \otimes \varepsilon_n}(x) \) is finite almost everywhere. So we will assume that this is finite on \( X \setminus N \), and that \( |D_K(x)| \leq \|K\| \) for \( x \) in \( X \setminus N \) for all \( K \) in \( \mathcal{K} \). For each \( x \) in \( X \setminus N \), the map on \( K_0 \) given by \( \phi_x(K) = D_K(x) \) is a linear map such that \( |\phi_x(K)| \leq \|K\| \). Thus \( \phi_x \) extends to a norm one positive linear functional on \( \mathcal{K} \). So there is a positive trace class operator \( D(x) \) of norm at most one so that \( \phi_x(K) = \text{tr} D(x)K \). Hence
\[ \text{tr} Q(\Delta)K = \mu(K(\Delta)) = \int_\Delta \text{tr}(D(x)K)dx = \int_\Delta D \, d\tau K \]

for all \( K \) in \( K_0 \). By the Hahn-Banach Theorem, \( Q(\Delta) = \int_\Delta D \, d\tau \). Finally

\[ \|Q(X)\|_1 \leq \int_\Delta \|D\|_1d\tau \leq \int d\tau = \|Q(X)\|_1. \]

So \( \|D(x)\|_1 = 1 \) a.e.\( \tau \). \( \Box \)

**16.19 Theorem.** Let \( \mathcal{N} \) be a nest on a separable space, and let \( T \) be a trace class operator in \( \mathcal{T}(\mathcal{N}) \). Then there is a regular Borel measure \( \tau \) on \( \mathcal{N} \) with \( \|\tau\| = \|T\|_1 \), and a Borel function \( T_N \) with values in \( b_1(\mathcal{C} \cap \mathcal{T}(\mathcal{N})) \) such that \( T_N = P(N)T_NP(N)^\perp \), \( T = \int T_N d\tau(N) \), and \( \|T\|_1 = \int \|T_N\|_1d\tau(N) \).

**Proof.** Let \( T = UQ \) be the polar decomposition of \( T \). By Theorem 16.16 and Corollary 16.17, there is a positive trace class valued measure \( Q(\cdot) \) such that \( Q[N,M] \) agrees with definition 14.15. From the proof of Lemma 16.1, \( UQ[N,M] \) belongs to \( \mathcal{T}(\mathcal{N}) \cap \mathcal{P}(\mathcal{M}) \mathcal{P}(\mathcal{N})^\perp \) for every pair \( N \leq M \) in \( \mathcal{N} \). By Theorem 16.18, there is a Borel function \( D(N) \) of positive, norm one trace class operators such that \( Q(\Delta) = \int_\Delta D \, d\tau \) where \( \tau(\Delta) = \text{tr} Q(\Delta) \). Let \( T(N) = UD(N) \). Then

\[
T = UQ = \int UD \, d\tau = \int T(N) d\tau(N)
\]

and

\[
\|T\|_1 \leq \int \|T(N)\|_1 d\tau \leq \int \|D(N)\|_1 d\tau = \|Q\|_1 = \|T\|_1.
\]

Now if a pair \( N \leq M \) belong to \( N \), then for every interval \([N',M']\) contained in \([N,M]\) one has

\[
\]

Thus \( UQ(\Delta) = P(M)UQ(\Delta)P(N)^\perp \) for every Borel subset \( \Delta \) of \([N,M]\). So

\[
\int_\Delta P(M)D(L)P(N)^\perp d\tau(L) = \int_\Delta D(L) d\tau(L)
\]

for all such \( \Delta \). Hence \( D(L) = P(M)D(L)P(N)^\perp \) a.e.\( \tau \) for \( L \) in \([N,M]\).

Let \( \{[N_k,M_k], k \geq 1\} \) be a countable dense set of pairs in the set of intervals of \( \mathcal{N} \). Then one can delete a set \( Z \) of \( \tau \)-measure zero so that off this set one has \( D(L) = P(M_k)D(L)D(N_k)^\perp \) whenever \( N_k \leq L < M_k \) and \( L \) belongs to \( \mathcal{N} \setminus Z \). Since these pairs are dense, one obtains \( D(L) = P(L_k)D(L)P(L)^\perp \).

In spite of this positive result, there are trace class operators in uncountable nests which are not exactly decomposable.
16.20 Lemma. Let $Q$ be a positive trace class operator. If $Q = Q_1 + Q_2$ and $\|Q\|_1 = \|Q_1\|_1 + \|Q_2\|_1$, then $Q_1$ and $Q_2$ are both positive.

Proof. $\|Q\|_1 = tr Q = tr Q_1 + tr Q_2 \leq \|Q_1\|_1 + \|Q_2\|_1 = \|Q\|$. Hence $\|Q_i\| = tr Q_i$. Now if $T = \sum_{n=1}^\infty s_n e_n \otimes f_n^*$ is trace class with $s$-numbers $s_n$, one has $\|T\|_1 = \sum_{n=1}^\infty s_n$. If $tr T = \|T\|_1$, then

$$\|T\|_1 = tr T = \sum_{n=1}^\infty s_n (e_n, f_n) \leq \sum_{n=1}^\infty s_n \|e_n\| \|f_n\| = \|T\|_1.$$ 

This forces $e_n = f_n$, so $T$ is positive. Thus both $Q_1$ and $Q_2$ are positive. ■

16.21 Lemma. Let $T = \begin{bmatrix} A & B \\ 0 & 0 \end{bmatrix}$ be a trace class operator on $\mathcal{H}_1 \oplus \mathcal{H}_2$. Suppose that $\text{Ran} A$ is dense on $\mathcal{H}_1$. Suppose $T = T_1 + T_2$ where $T_1 = \begin{bmatrix} A & C \\ 0 & 0 \end{bmatrix}$ and $T_2 = \begin{bmatrix} 0 & B-C \\ 0 & 0 \end{bmatrix}$, and $\|T\|_1 = \|T_1\|_1 + \|T_2\|_1$. Then $T_2 = 0$.

Proof. Let $T = UQ$ be the polar decomposition of $T$, and let $Q_i = U^* T_i$. Then $Q = Q_1 + Q_2$ and $\|Q\|_1 \geq \|Q_1\|_1 + \|Q_2\|_1 \geq \|Q\|_1$. So by Lemma 16.20, both $Q_i$ are positive. Since $\|Q_i\|_1 = \|T_i\|_1$, it follows that $T_i = UQ_i$. Now $Q_2$ has the form $U^* \begin{bmatrix} 0 & * \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} 0 & * \\ 0 & 0 \end{bmatrix}$, and thus the (1,2) entry is also 0. Hence $Q_1$ agrees with $Q$ except possibly in the (2,2) entry. One will have $Q_1 = Q$ if it can be shown that $Q$ is the smallest positive operator of the form $\begin{bmatrix} Q_{11} & Q_{12} \\ Q_{21} & * \end{bmatrix}$.

Now $Q^2 = T^* T = \begin{bmatrix} A^* & B^* \\ C^* & D^* \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix}$. Let $X = (AA^* + BB^*)^\alpha$. Since $AA^* \leq X^2$ and $BB^* \leq X^4$, Lemma 10.1 implies that there are norm one operators $C$ and $D$ so that $A = XC$ and $B = XD$. So

$$X^4 = AA^* + BB^* = X(CC^* + DD^*)X.$$

By hypothesis, $\text{Ran}(X)$ is dense in $\mathcal{H}_1$, so $X$ is one to one. Thus $CC^* + DD^* = X^2$. We claim that $Q = \begin{bmatrix} C & D \\ C^* & D^* \end{bmatrix} = \begin{bmatrix} C^*C & C^*D \\ D^*C & D^*D \end{bmatrix}$. To see this, compute
\[
\begin{bmatrix}
C^* C & C^* D \\
D^* C & D^* D
\end{bmatrix}^2 = \begin{bmatrix} C^* \\ D^* \end{bmatrix} \begin{bmatrix} C & D \\
C & D
\end{bmatrix} \begin{bmatrix} C^* \\ D^* \end{bmatrix} = \begin{bmatrix} C^* \\ D^* \end{bmatrix} \begin{bmatrix} X^2 & C D \\
D^* X^2 & A^* B
\end{bmatrix} = \begin{bmatrix} A^* \\ B^* \end{bmatrix} \begin{bmatrix} A & B \end{bmatrix} = Q^2.
\]

Now \( \text{Ran} \, C = \text{Ran} \, A = \mathcal{H}_1 \), so by the second half of Lemma 14.13, \( Q \) is the smallest positive operator of the form \[
\begin{bmatrix}
C^* C & C^* D \\
D^* C & *
\end{bmatrix}.
\]
Hence \( Q_1 = Q \), and \( Q_2 = 0 = T_2 \).

**18.22 Corollary.** Let \( T = \begin{bmatrix} T_{11} & T_{12} \\
0 & T_{22} \end{bmatrix} \) be a trace class operator on \( \mathcal{H}_1 \oplus \mathcal{H}_2 \) such that either \( \text{Ran} \, T_{11} = \mathcal{H}_1 \) or \( \ker T_{22} = \{0\} \). Then the exact decomposition \( T = T_1 + T_2 \) with \( \|T\| = \|T_1\| + \|T_2\| \), \( T_1 = \begin{bmatrix} T_{11} & Y_1 \\
0 & 0 \end{bmatrix} \), and \( T_2 = \begin{bmatrix} 0 & Y_2 \\
0 & T_{22} \end{bmatrix} \) is unique. So if both \( T_{11} \) and \( T_{22} \) are non-zero, one cannot write \( T = R + S \) with \( \|T\| = \|R\| + \|S\| \) and \( R = \begin{bmatrix} 0 & * \\
0 & 0 \end{bmatrix} \neq 0 \).

**Proof.** First assume that \( \ker T_{22} = \{0\} \), and suppose \( T = T_1 + T_2 \) as described. Let \( T = UQ \) be the polar decomposition, and set \( Q_i = U^* T_i \), \( i = 1, 2 \). As in Lemma 16.21, it follows that \( Q_1 \) and \( Q_2 \) are positive and \( Q_2 \) has the form \( \begin{bmatrix} 0 & 0 \\
0 & * \end{bmatrix} \). Thus the decomposition produced in Lemma 16.1 has the minimal possible choice of \( Q_1 \). Let us fix \( Q_1 \) and \( Q_2 \) as in Lemma 16.1. Non-uniqueness can occur only if there is a positive operator \( 0 \neq Q' \leq Q_2 \) such that \( UQ' \) has the form \( \begin{bmatrix} 0 & * \\
0 & 0 \end{bmatrix} \). Equivalently, this occurs only if \( T_2 = \begin{bmatrix} 0 & Y_2 \\
0 & T_{22} \end{bmatrix} \) has a non-trivial exact decomposition of the form \( \begin{bmatrix} 0 & * \\
0 & * \end{bmatrix} + \begin{bmatrix} 0 & 0 \\
0 & 0 \end{bmatrix} \). Taking adjoints puts this into the form of Lemma 16.21, and \( \text{Ran} \, T_{22} = (\ker T_{22})^\perp = \mathcal{H}_2 \). So Lemma 16.21 shows that this decomposition is unique.

If instead, \( \text{Ran} \, T_{11} \) is dense in \( \mathcal{H}_1 \), note that \( T^* \) is unitarily equivalent to \( \begin{bmatrix} T_{22} & T_{12} \\
0 & T_{11} \end{bmatrix} \) and \( \ker T_{11}^* = 0 \). So the first case shows that the decomposition is unique.
If $T$ decomposed as $R+S$ with $R = \begin{bmatrix} 0 & * \\ 0 & 0 \end{bmatrix} \neq 0$, decompose $S$ by Lemma 16.1 as $S_1+S_2$. Then $T = (S_1+R)+S_2 = S_1+(R+S_2)$ gives two different exact decompositions, contrary to fact. ■

**16.23 Theorem.** Let $\mathcal{N}$ be an uncountable nest on a separable space. Then $\mathcal{T}(\mathcal{N})_\perp$ contains trace class operators which are not exactly decomposable into a sum of rank one operators in $\mathcal{T}(\mathcal{N})$.

**Proof.** First, suppose that $\mathcal{N}$ is not purely atomic. Let $x$ be a vector supported on the continuous part, and let $P$ be the projection onto $\mathcal{N}_x$. Then $P$ commutes with $\mathcal{N}$, and $\mathcal{N}_0 = P\mathcal{N}|P\mathcal{N}$ is a continuous nest with cyclic vector. By Proposition 7.17, $\mathcal{N}_0$ is unitarily equivalent to the Volterra nest $\mathcal{M}$ on $L^2(0,1)$. If $T$ belongs to $\mathcal{T}(\mathcal{N}_0)_\perp$, then $PTP$ belongs to $\mathcal{T}(\mathcal{N})_\perp$. An exact decomposition $PTP = \sum R_n$ in $\mathcal{T}(\mathcal{N})_\perp$ leads to the exact decomposition $T = \sum R_n$ in $\mathcal{T}(\mathcal{N}_0)_\perp$. We show that certain operators in $\mathcal{T}(\mathcal{M})$ are not exactly decomposable.

Let $V$ be the usual Volterra operator (see Chapter 5). Now $V$ is a Hilbert-Schmidt operator in $\mathcal{T}(\mathcal{M})$, so $V^2$ belongs to $\mathcal{T}(\mathcal{M}) \cap C_1$ which equals $\mathcal{T}(\mathcal{M})_\perp$. $\mathcal{M}$ has no atoms. For each $M_t$ in $\mathcal{M}$, $V_t = P(M_t)V|M_t$ has no kernel so $V_t^2 = P(M_t)V^2$ has no kernel. Thus by Corollary 16.22, $V^2$ cannot be written as $V^2 = R+S$ where $R = P(M_t)R P(M_t) \perp \neq 0$ and $\|R\|_1 + \|S\|_1 = \|V^2\|_1$. This holds for every $t$ in $(0,1)$. As every rank one operator has this form, it follows that if $R$ is rank one in $\mathcal{T}(\mathcal{N})$ then

$$\|V^2-R\|_1 + \|R\|_1 > \|V^2\|_1.$$  

So $V^2$ does not have an exact decomposition.

If $\mathcal{N}$ is atomic but uncountable, there is a projection $P$ in $\mathcal{N}$ so that $\mathcal{N}_0 = R\mathcal{N}|P\mathcal{N}$ has a dense order on its atoms, each of which is one dimensional. (Such a nest is unitarily equivalent to the Cantor nest of Example 2.6.) Let the atoms be $\{E_n, n \geq 1\}$ and let the order on the atoms be $\ll$. Choose a sequence $a_n$ of positive real numbers such that $\sum_{n=1}^{\infty} a_n \leq 1$. Let $\{E_{nm}\}$ be a set of matrix units, and define a trace class operator in $\mathcal{T}(\mathcal{N}_0)$ by $T = \sum a_n e^* a_n e_n$. Let $e_n$ be a unit vector in $E_n$ and set $x = \sum_{n\geq 1} a_n e_n$. Let $N$ belong to $\mathcal{N}_0$. Because the order is dense, either $N = N_-$ or $N = N_+$. If $N = N_-$, it follows that the range of $T|N$ equals $\text{span}\{P(M)x: 0 \leq M \leq N\}$. This is all of $N$. Similarly, if $N = N_+$, the range of $T|N_\perp$ is $\text{span}\{P(M)x: N \leq M \leq \mathcal{N}\}$ which is all of $N_\perp$. As before, Corollary 16.22 implies that there are no rank one operators $R$ in $\mathcal{T}(\mathcal{N}_0)_\perp$ such that $\|T\|_1 = \|T-R\|_1 + \|R\|_1$. By Lemma 16.14, it does not
even have an exact decomposition in $\mathcal{T} (\mathcal{N})$. Again, as in the first paragraph, one deduces that $\mathcal{P} \mathcal{P} \mathcal{T}$ does not have an exact decomposition in $\mathcal{T} (\mathcal{N})$.

**Notes and Remarks.**

Lemma 16.1 is due to Lance [2] who used it to give the proof 16.8 of the distance formula. Theorem 16.6 is due to Fall-Arveson-Muhly [1]. The treatment leading to Theorem 16.6 independent of Erdos' Density Theorem or Ringrose's characterization of the radical is due to Power [9], as are the proofs of 16.7 and 16.9. The decomposition results Corollary 16.10 through Theorem 16.19 are due to Power [2]. The failure of exact decomposition, Theorem 16.28, is new.

**Exercises.**

16.1 Prove that the unit ball of $\mathcal{T} (\mathcal{N}) \cap C_1$ is the norm closed convex hull of its rank one operators.

16.3 Let $\mathcal{N}$ be a countable nest. Describe the measure $Q(\cdot)$ and the integral of Theorem 16.18 in terms of the notation of Theorem 16.13.

16.4 Derive the analogue of Theorem 16.18 for $\mathcal{T} (\mathcal{N})_\perp$. 
17. Isomorphisms

In this chapter, we classify the isomorphisms between two nest algebras and between two quasitriangular algebras. We make use of two important features: a nest algebra contains a maximal abelian von Neumann algebra (necessarily intermediate to \( \mathcal{N}'' \) and \( \mathcal{D}(\mathcal{N}) \)) and an adequate supply of rank one operators. To make use of rank one operators, it is shown that they are characterized algebraically within \( \mathcal{T}(\mathcal{N}) \). It will be shown that every isomorphism \( \alpha \) of one nest algebra onto another is spatial, meaning that there is an invertible operator \( S \) so that \( \alpha = Ad S \) where \( Ad S(X) = SXS^{-1} \) for every \( X \). In particular, these isomorphisms are always continuous in both the norm and weak* topologies. Then the structure of the outer automorphism groups of \( \mathcal{T}(\mathcal{N}) \) and \( Q \mathcal{T}(\mathcal{N}) \) will be computed.

17.1 Theorem. Let \( G \) be an amenable group. Then every representation of \( G \) on a Hilbert space bounded by \( K \) is similar to a unitary representation by a positive operator \( S \) satisfying \( K^{-1}I \leq S \leq KI \).

Proof. Let \( m \) be an invariant mean on \( L^\infty(G) \), and let \( V_g \) be a bounded representation of \( G \) on \( \mathcal{H} \). Let \( K = \sup \{ \| V_g \| : g \in G \} \). Define an inner product on \( \mathcal{H} \) by defining

\[
F_{x,y} (g) = (V^*_g x, V^*_g y)
\]

and setting \( \langle x, y \rangle = m(F_{x,y}) \). It is routine to verify that this is a sesquilinear form. Moreover,

\[
|\langle x, y \rangle| \leq \sup_g |(V^*_g x, V^*_g y)| \leq K^2 \| x \| \| y \|
\]

and

\[
|\langle x, x \rangle| \geq \inf_g |(V^*_g x, V^*_g x)| \geq K^{-2} \| x \|^2 .
\]

Thus there is a positive operator \( S \) with \( K^{-1}I \leq S \leq KI \) such that

\[
\langle x, y \rangle = (S^2 x, y) = (Sx, Sy) .
\]

The invariance of \( m \) implies that for \( h \) in \( G \),

\[
\langle V^*_h x, V^*_h y \rangle = m(F_{x,y}) = m(F_{x,y}) = \langle x, y \rangle .
\]

Thus
\[(SV_h^* S^{-1} x, SV_h^* S^{-1} y) = \langle V_h^* S^{-1} x, V_h^* S^{-1} y \rangle\]
\[= \langle S^{-2} x, S^{-1} y \rangle = (x, y).\]

Hence \(V_h^* S^{-1}\) is unitary, and consequently \(S^{-1} V_h S\) is unitary for every \(h\) in \(G\).

**17.2 Corollary.** Every bounded abelian group of operators on Hilbert space is similar to a group of unitary operators.

**Proof.** By Theorem 8.7, every abelian group is amenable.

A Boolean algebra of idempotents on Hilbert space is a commuting family \(B\) of idempotents containing 0 and \(I\) which is complemented \((P \in B\) implies \(I-P \in B)\) and is closed under lattice operations \(P \wedge Q = PQ\) and \(P \vee Q = P+Q-P\cdot Q\). This latter equation is redundant since
\[I-(P \vee Q) = (I-P) \wedge (I-Q).\]

Notice that \(Ran\ (P \wedge Q)\) is the intersection of \(Ran\ P\) and \(Ran\ Q\), and \(Ran\ (P \vee Q)\) is the span of those two subspaces.

**17.3 Corollary.** Let \(B\) be a Boolean algebra of idempotents on Hilbert space bounded by \(M\). Then there is a positive, invertible operator \(S\) with \((2M)^{-1} I \leq S \leq (2M) I\) such that \(SBS^{-1}\) consists of orthogonal projections.

**Proof.** The set \(\{2P-I : P \in B\}\) is an abelian group since
\[(2P-I)(2Q-I) = 2(2PQ-P-Q+I)-I\]
\[= 2((P \wedge Q) \vee [(I-P) \wedge (I-Q)])-I,
\]
and in particular, \((2P-I)^2 = I\). Also,
\[\|2P-I\| \leq \|P\| + \|I-P\| \leq 2M.\]

Let \(S\) be obtained by applying Theorem 17.1. For \(P\) in \(B\), \(P' = SPS^{-1}\) is idempotent and normal, and hence is an orthogonal projection.

**17.4 Theorem.** Let \(A\) and \(B\) be two maximal abelian von Neumann algebras, and let \(\alpha\) be an algebra isomorphism of \(A\) onto \(B\). Then there is a unitary operator \(U\) such that \(\alpha = Ad U\).

**Proof.** The isomorphism preserves spectrum and hence spectral radius. As \(A\) and \(B\) are abelian, every element is normal so has norm equal to the spectral radius. Hence \(\alpha\) is isometric. If \(P\) is a projection in \(A\), then \(\alpha(P)\) is an idempotent in \(B\) and thus also a projection. Let \(A = \sum_{i=1}^{n} a_i P_i\) be a linear combination of projections in \(A\). Then
\[ \alpha(A^\circ) = \sum_{i=1}^{n} \alpha(P_i) = (\sum_{i=1}^{n} \alpha(P_i))^* = \alpha(A)^* . \]

The elements \( A \) of this form are dense in \( \mathcal{A} \), and hence \( \alpha \) is a \( * \)-isomorphism.

Now let \( \{ A_i, i \in I \} \) be a bounded set of positive elements of \( \mathcal{A} \) with supremum \( A \). It will be shown that \( \alpha(A) \) is the supremum of \( S = \{ \alpha(A_i), i \in I \} \). First, \( \alpha \) preserves spectrum, hence it preserves positivity and order. So \( A_i \leq A \) implies \( \alpha(A_i) \leq \alpha(A) \), and hence \( \alpha(A) \) is an upper bound for \( S \). Suppose that \( B \) is any upper bound for \( S \). Then \( A_i \leq \alpha^{-1}(B) \) for every \( i \). Hence \( A \leq \alpha^{-1}(B) \), whence \( \alpha(A) \leq B \). So \( \alpha(A) \) is the supremum of \( S \). In particular, if \( P_n \) is a countable family of pairwise orthogonal projections in \( \mathcal{A} \), one obtains countable additivity:

\[ \alpha(s - \sum_{n=1}^{\infty} P_n) = s - \sum_{n=1}^{\infty} \alpha(P_n) . \]

It is clear that \( \mathcal{A} \) and \( B \) may be replaced by unitarily equivalent algebras without loss. By Theorem 7.8, it can then be assumed that there is a finite regular Borel space \( (X, \mu) \) so that \( \mathcal{A} \) is given by the canonical representation of \( L^\infty(\mu) \) acting on \( L^2(\mu) \). Likewise, we can suppose that there is a finite Borel space \( (Y, \nu) \) so that \( B \) acts as \( L^\infty(\nu) \) on \( L^2(\nu) \). Define a measure \( \bar{\mu} \) on the Borel sets of \( Y \) by

\[ \bar{\mu}(Y) = \| \alpha^{-1}(\chi_Y) \|_2^2 . \]

That is, the characteristic function \( \chi_Y \) is sent by \( \alpha^{-1} \) to an idempotent, hence characteristic function, \( \chi_X \) in \( L^\infty(\mu) \) and \( \bar{\mu}(Y) = \mu(X) \). The countable additivity of \( \bar{\mu} \) follows from the previous paragraph. Furthermore, if \( \nu(Y) = 0 \), then \( \alpha^{-1}(\chi_Y) = 0 \) so \( \bar{\mu}(Y) = 0 \); and if \( \nu(Y) \neq 0 \), then \( \alpha^{-1}(\chi_Y) \neq 0 \) so \( \bar{\mu}(Y) \neq 0 \). Consequently, \( \nu \) and \( \bar{\mu} \) are mutually absolutely continuous.

By the Radon-Nikodym Theorem, there is a strictly positive, integrable function \( h \) in \( L^1(\nu) \) such that \( \bar{\mu} = h d\nu \). Define a map \( U \) from simple functions on \( X \) into \( L^2(\nu) \) by

\[ UF = h^* \alpha(f) . \]

If \( \chi_X \) is a characteristic function, then \( \alpha(\chi_X) = \chi_Y \) in \( B \) and

\[ \| \chi_X \|_2^2 = \| \alpha^{-1}(\chi_Y) \|_2^2 = \bar{\mu}(Y) \]

\[ = \int \chi_Y h d\nu = \int |U_{XX}|^2 d\nu = \| U_{XX} \|_2^2 . \]

Thus if \( X_i \) are pairwise disjoint, one can choose disjoint \( Y_i \) so that \( \alpha(\chi_{X_i}) = \chi_{Y_i} \). Hence if \( f = \sum_{i=1}^{n} a_i \chi_{X_i} \)
\[\|Uf\|_2^2 = \|\sum_{i=1}^{n} a_i h^{\lambda_i} x_{\lambda_i}\|_2^2 = \sum_{i=1}^{n} |a_i|^2 \|h^{\lambda_i} x_{\lambda_i}\|_2^2 = \sum_{i=1}^{n} |a_i|^2 \|x_{\lambda_i}\|_2^2 = \|f\|_2^2.\]

It follows easily that \(U\) is an isometric map from the simple functions of \(L^2(\mu)\) onto a dense subset of \(L^2(\nu)\). Hence it extends to a unitary operator of \(L^2(\mu)\) onto \(L^2(\nu)\) which we also denote by \(U\). In particular, if \(f\) is in \(L^\infty(\mu)\), one still has \(Uf = h^{\lambda} \alpha(f)\).

Let \(f\) and \(g\) belong to \(L^\infty(\mu)\). Then
\[(UM_g U^*)f = U M_g f = U g f = h^{\lambda} \alpha(g) \alpha(f) = M(\alpha(g) \alpha(f)) = M \alpha(\{g\}) U f.\]

The vectors of the form \(Uf\) for \(f\) in \(L^\infty(\mu)\) are dense in \(L^2(\nu)\), and hence \(UM_g U^* = \alpha(M_g)\) for every \(g\) in \(L^\infty(\mu)\). That is, \(\alpha = Ad U\).

Now we turn our attention to non self-adjoint algebras. In particular, consider algebras \(A\) which are reflexive and contain a maximal abelian von Neumann algebra \(M\) (masa). The invariant subspaces lattice \(L = \text{Lat } A\) is a sub lattice of \(\text{Lat } M = \text{Proj } M\), the projection lattice of \(M\). Hence the orthogonal projections onto elements of \(L\) all commute. These lattices are called commutative subspace lattices (CSL). These lattices will be investigated more thoroughly in Chapter 22. For the moment, our interest lies only in the fact that this class contains all nest algebras.

17.5 Theorem. Let \(L_1\) and \(L_2\) be commutative subspace lattices and let \(\alpha\) be an isomorphism of \(\text{Alg } L_1\) onto \(\text{Alg } L_2\). Fix a masa \(M\) in \(\text{Alg } L_1\). Then there is an invertible operator \(S\) and an automorphism \(\beta\) of \(\text{Alg } L_1\) such that \(\alpha = Ad S \circ \beta\) and \(\beta(M) = M\) for all \(M\) in \(\mathcal{M}\).

Proof. Since \(M\) is a maximal abelian subalgebra of \(B\) and a fortiori of \(\text{Alg } L_1\), it follows that \(\alpha(M)\) is maximal abelian in \(\text{Alg } L_2\). The norm closure (even weak operator closure) of \(\alpha(M)\) is abelian and contains \(\alpha(M)\), so \(\alpha(M)\) is norm closed. Let \(\phi\) be the restriction isomorphism of \(M\) onto \(\alpha(M)\). For every \(M\) in \(\mathcal{M}\),
\[\sigma(M) = \sigma(M) = \sigma(\alpha(M)(\phi(M)))\]

The norm in \(\mathcal{M}\) is equal to the spectral radius, and the spectral radius is a lower bound for the norm in \(\alpha(M)\). Hence \(||\phi(M)|| \geq ||M||\) for every \(M\) in \(\mathcal{M}\). Consequently, \(\phi^{-1}\) is contractive and thus a continuous bijection of one Banach space onto another. By Banach's Isomorphism Theorem, \(\phi\) is continuous.

Let \(U\) be the unitary group of \(\mathcal{M}\). Then \(\phi(U)\) is a bounded abelian group of operators. By Corollary 17.2, there is an invertible operator \(T\) so that \(T \phi(U) T^{-1}\) is a group of unitaries. Let \(B = T \phi(M) T^{-1}\). Since \(M\) is spanned by \(U\), it follows that \(B\) is spanned by the abelian unitary group
$T\phi(U)T^{-1}$. Hence it is an abelian von Neumann algebra. Moreover, it is maximal abelian in the algebra $\mathcal{A} = T(\text{Alg } L_2)T^{-1} = \text{Alg } (TL_2)$.

Let $P$ be a projection onto an element $L$ of $L_2$. Then $P$ belongs to $\text{Alg } L_2$ and $Q = \alpha^{-1}(P)$ is an idempotent in $\text{Alg } L_1$. Furthermore, if $A$ belongs to $\text{Alg } L_1$,

$$\alpha((I-Q)AQ) = P^\perp \alpha(A)P = 0$$

Hence, the range of $Q$ is invariant for $\text{Alg } L_1$ and consequently for $\mathcal{M}$. So there is a projection $R$ in $\mathcal{M}$ with the same range, characterized by the identities $RQ = Q$ and $QR = R$. Hence $R' = T\alpha(R)T^{-1}$ is an idempotent (hence projection) in $\mathcal{B}$. Let $Q' = TPT^{-1}$, which is an idempotent with range $TL$. Since $R'R' = Q'$ and $Q'R' = R'$, it follows that $R'$ is the orthogonal projection onto $TL$.

Now we show that $\mathcal{B}$ is maximal abelian. Let $X$ belong to $B'$. Then $X$ commutes with the projection $R'$ onto each element in $TL_2$. So $X$ belongs to $\mathcal{A}$ and thus belongs to $\mathcal{B}$. Consequently, $AdT\alpha\phi$ is an algebra isomorphism between two masas. By Theorem 17.4, it has the form $AdU$ where $U$ is unitary. Let $S = T^{-1}U$, and $\beta = AdS^{-1}\circ\alpha$. Clearly, $\alpha = AdSo\beta$. Moreover, the restriction of $\beta$ to $\mathcal{M}$ equals $AdU^*cAdT\phi$ which is the identity. It remains to show that $\beta$ takes $\text{Alg } L_1$ onto itself.

If $P$ is the orthogonal projection onto an element $L$ of $L_1$, then $P$ belongs to $\mathcal{M}$. Hence for any $A$ in $\text{Alg } L_1$,

$$0 = \beta(P^\perp AP) = P^\perp \beta(A)P$$

Thus $\beta(A)$ belongs to $\text{Alg } L_1$. On the other hand, if $P$ is a projection onto an invariant subspace of $\beta(\text{Alg } L_1)$, then it is in particular invariant for $\mathcal{M}$ and thus $P$ belongs to $\mathcal{M}$. So for $A$ in $\text{Alg } L_1$,

$$0 = P^\perp \beta(A)P = \beta(P^\perp AP)$$

And thus the range of $P$ belongs to $\text{Lat } (\text{Alg } L_1)$. (It is true but not needed here that $\text{Lat } (\text{Alg } L_1) = L_1$. See Chapter 22.) In other words, $\text{Alg } L_1$ and $\beta(\text{Alg } L_1)$ have the same invariant subspace lattice. Since

$$\beta(\text{Alg } L_1) = S^{-1}a(\text{Alg } L_1)S = S^{-1}(\text{Alg } L_2)S = \text{Alg } (S^{-1}L_2)$$

one knows that $\beta(\text{Alg } L_1)$ is reflexive. Therefore, $\beta(\text{Alg } L_1) = \text{Alg } L_1$; so $\beta$ is an automorphism. \[\blacksquare\]

Now, we consider the usefulness of finite rank operators. The following lemma is very easy and the proof is omitted. It should be compared with the much more difficult proof in the nest algebra case (Lemma 17.9).

**17.6 Lemma.** An operator $T$ has rank one if and only if for all rank one operators $A$ and $B$, $ATB = 0$ implies either $AT = 0$ or $TB = 0$. 

17.7 Theorem. Let \(A\) and \(B\) be norm closed algebras containing the finite rank operators. Let \(\alpha\) be an isomorphism of \(A\) onto \(B\). Then there is an invertible operator \(S\) such that \(\alpha = \text{Ad} S\).

Proof. Lemma 17.6 characterizes rank one operators algebraically. So the isomorphism \(\alpha\) carries the set of rank one operators onto itself.

Fix a non-zero vector \(y\) in \(\mathcal{H}\). Since \(y \otimes y^*\) is rank one, there are vectors \(u\) and \(v\) so that \(\alpha(y \otimes y^*) = u \otimes v^*\). If \(x\) is any vector, \(\alpha(x \otimes y^*)\) is rank one of the form \(a \otimes b^*\). Hence
\[
\alpha(x \otimes y^*) = \alpha((x \otimes y^*)||y||^2(y \otimes y^*)) = ||y||^2(a \otimes b^*)(u \otimes v^*)
\]
\[
= ||y||^2(u,b)a \otimes v^* = u_x \otimes v^* .
\]
Furthermore, the linearity of \(\alpha\) shows that the map \(S\) taking \(x\) to \(u_x\) is linear. And \(S\) is one to one since \(\alpha\) is. Likewise, for each non-zero vector \(x\), there is a vector \(u\) and a linear one to one map \(T_x\) such that \(\alpha(x \otimes y^*) = u \otimes (T_x y)^*\). Hence \(S_x x\) is a multiple of \(u\) for every \(y\), and \(T_x y\) is a multiple \(v\) for every \(x\).

Pick unit vectors \(x_0\) and \(y_0\). For each \(y\), replace \(v\) and \(S\) by scalar multiples so that \(S_y x_0 = S_{y_0} x_0\) (which is non-zero since \(S_{y_0}\) is one to one). We show that \(S_y = S_{y_0}\). For if \(x\) is not a multiple of \(x_0\), there are constants \(c\) and \(d\) so that \(S_y x = c S_{y_0} x\) and \(S_y (x + x_0) = d S_{y_0} (x + x_0)\). Compute
\[
d S_{y_0} x + d S_{y_0} x_0 = S_y x + S_y x_0 = c S_{y_0} x + S_{y_0} x_0 .
\]
So
\[
(d - c) S_{y_0} x = (1 - d) S_{y_0} x_0 .
\]
But \(S_{y_0} x\) and \(S_{y_0} x_0\) are linearly independent, whence \(c = d = 1\). Let \(S\) be the operator \(S_{y_0} = S_y\). Now scale each \(T_x\) so that
\[
\alpha(x \otimes y^*) = S_x \otimes (T_x y)^* .
\]
As above, it follows that \(T_x = T_{x_0}\) for every \(x\). We will denote this by \(T\).

So, \(\phi(x \otimes y^*) = S_x \otimes (T y)^*\) for every \(x\) and \(y\) in \(\mathcal{H}\). As \(\alpha\) takes the rank one operators onto the rank one operators, \(S\) and \(T\) are surjective.

Now, apply the multiplicative nature of \(\alpha\) to \((x,y)x_0 \otimes y_0^* = (x_0 \otimes y_0^*)(x \otimes y_0^*)\) to obtain
\[
(x,y)S x_0 \otimes (T y_0)^* = (S x_0 \otimes (T y_0)^*)(S x \otimes (T y_0)^*)
\]
\[
= (S x, T y)S x_0 \otimes (T y_0)^* .
\]
Thus
\[(x,y) = (Sx,Ty) = (T^*Sx,y)\]

for every \(x\) and \(y\) in \(\mathcal{H}\). So \(T = (S^*)^{-1}\). So
\[
\alpha(x \otimes y^*) = Sx \otimes (S^*)^{-1}y = S(x \otimes y^*)S^{-1}.
\]

Let \(A\) be any element of \(\mathcal{A}\), and let \(x\) belong to \(\mathcal{H}\). One obtains
\[
S(Ax \otimes y_0)S^{-1} = \alpha(Ax \otimes y_0) = \alpha(A)\alpha(x \otimes y_0) = \alpha(A)S(x \otimes y_0^*)S^{-1}.
\]

Therefore \(SAx = \alpha(A)Sx\) for all \(x\) in \(\mathcal{H}\), so \(\alpha(A) = SAS^{-1}\).

It remains to show that \(S\) is continuous. For \(A\) in \(\mathcal{A}\) and \(x, y\) in \(\mathcal{H}\) one has
\[
|\alpha(A)\langle x, y \rangle| = |\langle AS^{-1}x, S^*y \rangle| \leq \|A\| \|S^{-1}x\| \|S^*y\|.
\]

Hence
\[
\sup_{\|A\| \leq 1} |\alpha(A)\langle x, y \rangle| \leq \|S^{-1}x\| \|S^*y\|.
\]

So, the set \(\{\alpha(A)\langle x \rangle : \|A\| \leq 1\}\) for fixed \(x\) as a set of functionals on \(\mathcal{H}\) are bounded pointwise. By the uniform boundedness principle,
\[
\sup_{\|A\| \leq 1} \|\alpha(A)x\| = C_x < \infty.
\]

A second application yields
\[
\sup_{\|A\| \leq 1} \|\alpha(A)\| < \infty.
\]

Thus \(\alpha\) is norm continuous. Let \(e\) be any unit vector. Then
\[
\|Sx\| = \|Sx \otimes e^*\| = \|\alpha(x \otimes (S^*e)^*)\| \leq \|\alpha\| \|S^*e\| \|e\|.
\]

So \(S\) is continuous, and likewise \(S^{-1}\) is continuous.

**17.8 Corollary.** Let \(\mathcal{H}\) and \(\mathcal{M}\) be nester. The \(QT(\mathcal{H})\) and \(QT(\mathcal{M})\) are isomorphic if and only if they are unitarily equivalent. Every such isomorphism is spatially implemented, and factors as \(\text{Ad}U\cdot\text{Ad}A\) where \(U\) is unitary and \(A\) is invertible in \(QT(\mathcal{H})\).

**Proof.** Since these algebras contain the finite rank operators, Theorem 17.7 shows that every isomorphism is spatial. If \(\alpha = \text{Ad}S\) is an isomorphism, then \(Q(T(\mathcal{M})) = \text{Ad}S(QT(\mathcal{H})) = QT(S\mathcal{H})\). By the similarity Theorem 13.20, there is a unitary operator \(U\) and a compact operator \(K\) with \(\|K\| < \frac{1}{4}\) such that \(SN = (U+K)N\) for every \(N\) in \(\mathcal{H}\). Thus \(U^*SN = (I+U^*K)N\) for every \(N\) in \(\mathcal{H}\). Since \(K\) is compact, \(Q(T((I+U^*K)\mathcal{H})) = QT(\mathcal{H})\). Thus
\[
UQT(\mathcal{H})U^* = QT((I+U^*K)\mathcal{H})U^* = QT((U+K)\mathcal{H}) = QT(\mathcal{M})\).
\]

Moreover, \(T = (I+U^*K)^{-1}U^*S\) is invertible in \(QT(\mathcal{H})\), hence
\[ A = (1+U^*K)T \text{ is invertible in } Q\mathcal{T}(\mathcal{K}). \text{ So } Ad S = Ad U. Ad T. \]

Now, we turn to nest algebras. The first step is an algebraic description of the rank one elements as in Lemma 17.6.

**17.9 Lemma.** Let \( \mathcal{N} \) be a nest, and let \( T \) belong to \( \mathcal{T}(\mathcal{N}) \). Then \( T \) has rank one if and only if whenever \( A \) and \( B \) belong to \( \mathcal{T}(\mathcal{N}) \) and \( ATB = 0 \), then either \( AT = 0 \), or \( TB = 0 \).

**Proof.** If \( T = x \otimes y^* \) is rank one, then \( ATB = Ax \otimes (B'y)^* \). So \( ATB = 0 \) if and only if \( Ax = 0 \) or \( B'y = 0 \). Since \( AT = Ax \otimes y^* \) and \( TB = x \otimes (B'y)^* \), it is clear that the latter condition is equivalent to \( AT = 0 \) or \( TB = 0 \).

Suppose \( T \) in \( \mathcal{T}(\mathcal{N}) \) has rank at least two. Let
\[
N' = \vee \{ N \in \mathcal{N} : \text{rank } TP(N) \leq 1 \}.
\]
Since the rank one operators are strongly closed, \( TP(N') \) has rank at most one and so \( N' \subset \mathcal{N} \). Choose any \( N_0 > N' \) for which \( (N_0)^- \neq \mathcal{N} \). Since \( TP(N_0) \) has rank at least two, one can repeat this process for its adjoint to obtain \( N_1 \) in \( \mathcal{N} \) so that \( (N_0)^- \neq \{0\} \) and \( T^* = P(N_1)^{-}TP(N_0) \) has rank at least two. Let \( S \) be the operator in \( B(N_0,N_1^-) \) agreeing with \( T^* \).

Pick any unit vector \( y \) in \( N_0 \) so that \( Sy \neq 0 \). Since \( (\ker S^*)^\perp \) has dimension at least two, it has non trivial intersection with \( (Sy)^\perp \). Choose a unit vector \( x \) in this intersection. Then \( x \) belongs to \( N_1^+ \) and satisfies \( T^* x \neq 0 \) but \( (Ty,x) = 0 \). Choose unit vectors \( z_0 \) in \( (N_0)^\perp \) and \( z_1 \) in \( (N_1)^+ \).

By Lemma 2.8, the operators \( A = z_1 \otimes z^* \) and \( B = y \otimes z_0^* \) belong to \( \mathcal{T}(\mathcal{N}) \). Furthermore, \( AT = z_1 \otimes (T^*x)^* \neq 0 \) and \( TB = Ty \otimes z_0^* \neq 0 \), yet \( ATB = (Ty,x)z_1 \otimes z_0^* = 0 \).

**17.10 Lemma.** Let \( A \) be a maximal abelian von Neumann algebra. Let \( z_n, n \geq 1 \) be vectors in \( \mathcal{A} \) such that \( \sum_{n=1}^{\infty} \| z_n \| < \infty \). Then there is a vector \( z \) and elements \( A_n \) in the unit ball of \( \mathcal{A} \) such that \( A_n z = x_n \) for \( n \geq 1 \).

**Proof.** By Theorem 7.8, \( A \) is unitarily equivalent to the canonical representation of \( L^\infty(\mu) \) on \( L^2(\mu) \) for a finite regular Borel measure \( \mu \). So \( x_n \) correspond to functions \( f_n \) in \( L^2(\mu) \). Let \( g = \sum_{n=1}^{\infty} |f_n| \), which belongs to \( L^2(\mu) \) and hence converges almost everywhere. Let \( h_n = g^{-1}f_n \) where \( h_n \) is defined to be zero on \( f_n^{-1}(0) \). By construction, \( \| h_n \|_{L^\infty(\mu)} \leq 1 \) and \( h_n g = f_n \). So choose \( z \) to correspond to \( g \), and \( A_n \) corresponding to \( M_{h_n} \).
17.11 Corollary. Let \( T \) be a linear map defined on all of \( \mathcal{H} \). If \( T \) commutes with every \( A \) in a masa \( \mathcal{A} \), then \( T \) belongs to \( \mathcal{A} \).

**Proof.** It suffices to prove that \( T \) is continuous. If it is not continuous, one can choose vectors \( x_n \) such that \( \|x_n\| \leq 2^{-n} \) and \( \|Tx_n\| \geq n \). Let \( z \) and \( A_n \) be provided by Lemma 17.10. Then for all \( n \),
\[
n \leq \|Tx_n\| = \|TA_n z\| = \|A_n Tz\| \leq \|Tz\| .
\]
This is impossible. So \( T \) is bounded. \( \blacksquare \)

17.12 Theorem. Let \( \mathcal{N} \) be a nest, and let \( \mathcal{A} \) be a masa contained in \( \mathcal{T}(\mathcal{N}) \). Suppose that \( \alpha \) is an automorphism of \( \mathcal{T}(\mathcal{N}) \) such that \( \alpha(A) = A \) for all \( A \) in \( \mathcal{A} \). Then there is an invertible element \( S \) in \( \mathcal{A} \) such that \( \alpha = Ad S \).

**Proof.** Let \( \mathcal{N}_1 \) denote all \( N \) in \( \mathcal{N} \) such that \( N \neq 0 \) and \( N_\perp \neq \mathcal{H} \). This consists of all \( N \neq 0 \) or \( \mathcal{H} \), together with \( \mathcal{H} \) if \( \mathcal{H} \) has an immediate predecessor. Fix \( N \) in \( \mathcal{N}_1 \). Let \( x \) belong to \( N \) and let \( y \) belong to \( (N_\perp)^\perp \). So \( x \otimes y^* \) belongs to \( \mathcal{T}(\mathcal{N}) \) by Lemma 3.7. By Lemma 17.6, \( \alpha(x \otimes y^*) \) is rank one, and thus can be written as \( u \otimes v^* \). Moreover,
\[
u \otimes v^* = \alpha(P(N)(x \otimes y^*)P(N_\perp)^\perp) = P(N)u \otimes (P(N_\perp)^\perp v)^* .
\]
So \( u \) belongs to \( N \) and \( v \) belongs to \( (N_\perp)^\perp \). The vectors \( u \) and \( v \) are unique up to a scalar \( \lambda \) since
\[
u \otimes v = (\lambda u) \otimes (\lambda^{-1} v)^* .
\]

Fix two unit vectors \( x_0 \) in \( N \) and \( y_0 \) in \( (N_\perp)^\perp \). Choose \( u_0 \) and \( v_0 \) so that \( \alpha(x_0 \otimes y_0^*) = u_0 \otimes v_0^* \). If \( x_1 \), \( x_2 \) belong to \( N_1 \), use Lemma 17.9 to obtain a vector \( x \) in \( N \) and \( A_i \) in \( \mathcal{A} \) so that \( A_i x = x_i \), \( 0 \leq i \leq 2 \). Let \( \alpha(x \otimes y_0^*) = u \otimes v^* \), normalized so that \( (u,v_0) = \|v_0\|^2 \). If \( \lambda_0 = 1, \lambda_1, \lambda_2 \) are scalars,
\[
\alpha(\sum_{i=1}^2 \lambda_i x_i \otimes y_0^*) = \alpha(\sum_{i=1}^2 \lambda_i A_i x \otimes y_0^*) = \sum_{i=1}^2 \lambda_i (A_i u) \otimes v^* .
\]

Taking \( \lambda_0 = 1, \lambda_1 = \lambda_2 = 0 \) yields \( u_0 \otimes v_0^* = A_0 u \otimes v^* \). The normalization guarantees that \( v = v_0 \) and \( A_0 u = u_0 \). Let \( u_i = A_i u \) for \( i = 1,2 \). Then \( \alpha(x_i \otimes y_0^*) = u_i \otimes v_0^* \). Consequently, \( u_i = U(x_i) \) is independent of the choice of \( x \). By (17.10.1), \( U \) is a linear map.

Similarly, there is a linear map \( V \) on \( (N_\perp)^\perp \) such that \( \alpha(x_0 \otimes y^*) = u_0 \otimes (Vy)^* \). Let \( y_i \) belong to \( (N_\perp)^\perp \). Let \( y \) belong to \( (N_\perp)^\perp \) and \( B_0, B_1 \) belong to \( \mathcal{A} \) such that \( B_i y = y_i \) for \( i = 0,1 \) (Lemma 17.9). Then as above, write \( \alpha(x \otimes y) = u \otimes v^* \) and compute
\[
\alpha((\lambda_0x_0 + \lambda_1x_1) \otimes (\mu_0y_0 + \mu_1y_1)) = (\lambda_0A_0 + \lambda_1A_1) \otimes y^*(\mu_0B_0 + \mu_1B_1)^*
= (\lambda_0A_0u + \lambda_1A_1u) \otimes (\mu_0B_0v + \mu_1B_1v)^*.
\]

With \(\lambda_0 = \mu_0 = 1\) and \(\lambda_1 = \mu_1 = 0\), one sees that \(u\) and \(v\) can be normalized so that \(A_0u = u_0\) and \(B_0v = v_0\). With this done, \(\lambda_0 = \mu_1 = 0\) and \(\lambda_1 = \mu_0 = 1\) yields \(A_1u = Ux_1\). Likewise, \(\lambda_0 = \mu_1 = 1\) and \(\lambda_1 = \mu_0 = 0\) yields \(B_1v = V y_1\). So plugging in \(\lambda_0 = \mu_0 = 0\) and \(\lambda_1 = \mu_1 = 1\) gives

\[\alpha(x_1 \otimes y_1) = Ux_1 \otimes (Vy_1)^* .\]

Next, notice that if \(u\) belongs to \(N\) and \(v\) belongs to \((N_\perp)^\perp\), then \(\alpha^{-1}(u \otimes v^*) = x \otimes y\) is rank one and as before, \(x\) belongs to \(N\) and \(y\) belongs to \((N_\perp)^\perp\). So \(Ux\) and \(Vy\) are multiples of \(u\) and \(v\) respectively. Hence \(U\) and \(V\) are surjective, as well as one to one since \(\alpha\) is one to one. If \(A\) belongs to \(\mathcal{A}\) and \(x\) is in \(N\),

\[UAx \otimes v_0^* = \alpha(Ax \otimes y_0^*) = A\alpha(x \otimes y_0^*) = A\alpha(x) \otimes y_0^* = AUx \otimes v_0^*.\]

So \(U\) (as an operator on \(N\)) commutes with the restriction of \(\mathcal{A}\) to \(N\) which is a masa. By Corollary 17.11, \(U\) belongs to \(\mathcal{A}\). Likewise \(V\) belongs to \(\mathcal{A}\). In particular, \(U\) is invertible in \(B(N)\) and \(V\) is invertible in \(B((N_\perp)^\perp)\).

So far, \(N\) has been fixed. For each \(N\), there are operators \(U_N\) in \(\mathcal{A} \upharpoonright N\) and \(V_N\) in \(\mathcal{A} \upharpoonright ((N_\perp)^\perp)\) such that

\[\alpha(x \otimes y^*) = U_Nx \otimes (V_Ny)^*\]

for all \(x\) in \(N\) and \(y\) in \((N_\perp)^\perp\). Suppose \(N_1 < N_2\) belong to \(\mathcal{H}\). Then for each \(x\) in \(N_1\) and \(y\) in \((N_2_\perp)^\perp\), one obtains

\[U_{N_2}U_Nx \otimes (V_{N_2}y)^* = U_Nx_2 \otimes (V_{N_2}y)^* .\]

Thus there is a non-zero scalar \(\lambda\) such that

\[U_{N_2}|N_1 = \lambda U_{N_1}|(N_2)^\perp = \bar{X}V_{N_2}.\]

Pick an \(N_0\) and replace \(U_N\) and \(V_N\) by scalar multiples so that they agree with \(U_{N_0}\) and \(V_{N_0}\) on their common domains. It follows that there is an operator \(U\) defined on \(\bigcup\{N \in \mathcal{N}: N < \mathcal{H}\}\) such that \(U|N = U_N\) for each \(N\). Likewise, there is an operator \(V\) defined on \(\bigcup\{N^\perp:N \neq 0\}\) such that \(V|N^\perp = V_N\). Furthermore,

\[\alpha(x \otimes y^*) = Ux \otimes (Vy)^*\]

for every rank one operator in \(\mathcal{T}(\mathcal{H})\).

Let \(x_1 \otimes y_1^*\) and \(x_2 \otimes y_2^*\) be two non-zero rank one operators in \(\mathcal{T}(\mathcal{H})\). Then
\[(x_2y_1)Ux_1 \otimes (Vy_2)^* = \alpha((x_1 \otimes y_1^*)(x_2 \otimes y_2^*)) = \alpha(x_1 \otimes y_1^*)\alpha(x_2 \otimes y_2^*) = (Ux_2, Vy_1)Ux_1 \otimes (Vy_2)^* .\]

Then,

\[(x_2y_1) = (Ux_2, Vy_1) = (V^*Ux_2, y_1) .\]

This holds for every \(x_2\) in \(N_2\) and \(y_1\) in \((N_-)^\perp\) and every \(N_1, N_2\) in \(\mathcal{H}\). Hence

\[V|N_2 \oplus (N_1)^\perp = (U|N_2 \oplus (N_1)^\perp)^{**-1} .\]

With \(N_2\) fixed, one has \(U|N_2\) is invertible so \(V\) is uniformly bounded on \(\bigcup\{N_2 \oplus (N_1)^\perp : N_1 > 0\}\), and thus \(V\) extends to be continuous on \(N_2\). As it is bounded on \((N_2)^\perp\), \(V\) is bounded on \(\mathcal{H}\). Likewise, \(U\) extends to be bounded on \(\mathcal{H}\). Moreover, \(V|N_2 = (U|N_2)^{**-1}\) and likewise \(V|(N_2)^\perp = (U|(N_2)^\perp)^{-1}\) so \(V = U^{**}\). In other words, \(U\) is an invertible operator in \(\mathcal{A}\) such that

\[\alpha(x \otimes y^*) = Ux \otimes (U^{**-1})^* = U(x \otimes y^*)U^{-1}\]

for every rank one operator in \(T(\mathcal{H})\).

Let \(T\) belong to \(T(\mathcal{H})\). For every \(x \otimes y^*\) in \(T(\mathcal{H})\)

\[U(Tx \otimes y^*)U^{-1} = \alpha(T(x \otimes y^*)) = \alpha(T)\alpha(x \otimes y^*) = \alpha(T)U(x \otimes y^*)U^{-1} .\]

Therefore, with \(u = Uz\), one has

\[(UTU^{-1} - \alpha(T))u = 0 .\]

This holds for every \(u\) in \(\bigcup\{N : N < \mathcal{H}\}\). This is dense in \(\mathcal{H}\), so \(\alpha(T) = UTU^{-1}\) for every \(T\) in \(T(\mathcal{H})\).

Combining Theorems 17.5 and 17.12, one immediately obtains

17.13 Corollary. Every isomorphism between nest algebras is spatial.

This is not the end of the story. Let \(\mathcal{H}\) be a nest and let \(\alpha = Ad S\) be an automorphism of \(T(\mathcal{H})\). Then

\[T(\mathcal{H}) = S T(\mathcal{H})S^{-1} = T(S \mathcal{H}) .\]

So \(\theta_S(N) = SN\) is a dimension preserving order isomorphism of \(\mathcal{H}\). If \(S\) is an invertible element of \(T(\mathcal{H})\), then \(\theta_S = id\). Conversely, if \(\theta_S = id\), then \(SN = N\) for every \(N\) and thus \(S\) and \(S^{-1}\) belong to \(T(\mathcal{H})\). The automorphisms \(Ad S\) for \(S\) in \(T(\mathcal{H})^{-1}\) are the inner automorphisms, denoted \(\text{Inn}(T(\mathcal{H}))\). This is a normal subgroup of \(\text{Aut}(T(\mathcal{H}))\) because \(\alpha Ad S \alpha^{-1} = Ad \alpha(S)\). The quotient group of the automorphism group
Aut(T(M)) by Inn(T(M)) is denoted Out(T(M)) for outer automorphism group. Let Aut(M) denote the group of dimension preserving order isomorphism of M.

17.14 Corollary. The map \( \Theta : S \rightarrow \theta_S \) of Aut(T(M)) into Aut(M) is surjective, and provides a natural isomorphism between Out T(M) and Aut(M).

Proof. The discussion prior to the statement shows that the kernel of \( \Theta \) is Inn(T(M)), and it is routine to verify that \( \Theta \) is a homomorphism. If \( \theta \) belongs to Aut(M), then by the Similarity Theorem 13.20, there is an invertible operator S such that \( \theta_S = \theta \). So \( \Theta \) is surjective. Hence Out T(M) is naturally isomorphic to Aut(M).

17.15 Corollary. If \( \alpha \) belongs to Aut(T(M)) and \( \|\alpha - \text{id}\| < 1 \), then \( \alpha \) is inner. Hence Inn(T(M)) is open and closed, and Out T(M) has the discrete topology.

Proof. If \( \alpha = \text{Ad}S \) is not inner, then \( \theta_S \neq \text{id} \). So there is some \( N \) in M with \( SN \neq N \). But then \( \alpha(P(N)) = SP(N)S^{-1} \) is an idempotent with range SN in M. Thus \( \|\alpha(P(N)) - P(N)\| \geq 1 \). (For example, if \( SN > N \), choose a unit vector \( x \) in \( SN \ominus N \). Then \( \alpha(P(N)) - P(N)x = x \).) So \text{id} is in the interior of Inn(T(M)). Hence Inn T(M) is open. The complement of Inn T(M) is the union of cosets, so is also open.

Now we analyze the outer automorphisms of Q T(M). The main tool is Theorem 12.8. The first step, Lemma 17.19, is to make the perturbations involved more restricted.

17.16 Lemma. Let \( N \) be a nest and let \( \Delta \) be the unique expectation onto \( D_\Delta(M) \), the atomic part of the diagonal. Suppose \( S \) is invertible, and let \( \Psi \) be the corresponding expectation onto \( D_\Psi(SM) \). Then \( \Psi \circ \text{Ad}S \mid D_\Delta(M) \) and \( \Delta \circ \text{Ad}S^{-1} \mid D_\Delta(SM) \) are isomorphisms, reciprocal to one another.

Proof. Let \( E = P(N_\Delta) - P(N) \) be an atom of M and let \( \tilde{E} = P(SN_\Delta) - P(SN) \) be the corresponding atom of SM. Let \( \Lambda = \tilde{E}SE \) as an element of \( B(EX, E\mathcal{H}) \). As an operator from \( N \oplus E\mathcal{H} \oplus N_\Delta^\perp \) to \( SN \oplus \tilde{E}N \oplus (SN_\Delta^\perp)_\perp \), S is upper triangular with \( A \) as its 2-2 entry. Likewise, \( S^{-1} \) is upper triangular from \( SN \oplus \tilde{E}N \oplus (SN_\Delta^\perp)_\perp \) to \( N \oplus E\mathcal{H} \oplus N_\Delta^\perp \). So a computation shows that its 2-2 entry must be \( A^{-1} \). If \( X \) belongs to \( B(E) \),
\[ \Psi \circ \text{Ad } S(\text{EXE}) = \Psi \begin{bmatrix} * & * & * \\ 0 & A & * \\ 0 & 0 & * \end{bmatrix} \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} * & * \\ 0 & A^{-1} \\ 0 & 0 \end{bmatrix} = \Psi \begin{bmatrix} * & * & * \\ 0 & AXA^{-1} & * \\ 0 & 0 & 0 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & AXA^{-1} & 0 \\ 0 & 0 & 0 \end{bmatrix} . \]

Similarly, if \( Y \) belongs to \( B(\hat{E}) \)
\[ \Delta \circ \text{Ad } S^{-1}(\hat{E}Y\hat{E}) = E(A^{-1}YA)E . \]

Summing over all atoms yields the lemma. ■

17.17 Corollary. With the same notation, \( \Psi \circ \text{Ad } S | \mathcal{D}_{\sigma}(\mathcal{M}) \cap \mathcal{M}^\sigma \) is a *-isomorphism onto \( \mathcal{D}_{\sigma}(S\mathcal{M}) \cap (S\mathcal{M})^\sigma \) with inverse \( \Delta \circ \text{Ad } S^{-1} | \mathcal{D}_{\sigma}(S\mathcal{M}) \cap (S\mathcal{M})^\sigma \).

Proof. \( \mathcal{D}_{\sigma}(\mathcal{M}) \cap \mathcal{M}^\sigma \) is the centre of \( \mathcal{D}_{\sigma}(\mathcal{M}) \) and hence is carried onto the centre of \( \mathcal{D}_{\sigma}(S\mathcal{M}) \), namely \( \mathcal{D}_{\sigma}(S\mathcal{M}) \cap (S\mathcal{M})^\sigma \). These two algebras are abelian von Neumann algebras. Projections are thus taken to projections. Hence on the span of the projections, one sees that adjoints are preserved. By continuity, these maps are *-isomorphisms. ■

17.18 Lemma. Let \( \mathcal{M} \) be a nest, \( S \) an invertible operator, and let \( F \) be a finite dimensional subspace such that \( P(F) \) commutes with \( S\mathcal{M} \). Then there is a subspace \( F_1 \) such that \( P(F_1) \) belongs to \( \mathcal{M}^\prime \) and an invertible compact perturbation \( S_1 \) of \( S \) so that \( S_1(N^{-1}) = (S\mathcal{M})^F \).

Proof. Let \( \Delta \) and \( \Psi \) be as in the previous lemma. Since \( P(F) \) is finite rank in \((S\mathcal{M})'\), there are finitely many atoms \( \hat{E}_1, \ldots, \hat{E}_n \) so that \( P(F) = \sum_{i=1}^{n} \hat{E}_iP(F)\hat{E}_i \). Hence

\[ R_1 = \Delta \text{Ad } S^{-1}(P(F)) = \sum_{i=1}^{n} \hat{E}_iS^{-1}P(F)S\hat{E}_i . \]

Let \( F_1 \) be the range of \( R_1 \). As \( F_1 \) is the direct sum of subspaces of atoms, \( P(F_1) \) belongs to \( \mathcal{M}^\prime \). Let

\[ S_1 = P(F)SP(F_1) + P(F)^\perp SP(F_1)^\perp . \]
This is a compact perturbation of $S$. Moreover, $R_i P(F_i) = P(F_i)$ and $P(F_i) R_i = R_i$. Let $R = \Psi \text{Ad} S(P(F))$. By Lemma 17.16, $\Psi \text{Ad} S(R) = P(F)$ whence $P(F) R = R$ and $R P(F) = P(F)$. So $R$ is an idempotent with range $F$. Thus $S_i F_1 = SF_1 = F$. As operators from $F_1 \oplus F_1^\perp$ to $F \oplus F^\perp$ and back, $S$ and $S^{-1}$ are triangular. So $S_1$ is invertible. If $N$ belongs to $\mathcal{N}$, $S_1 (F_1 \vee N) = F \vee SN$ belongs to $(S \mathcal{N})^\perp$. Hence $S_1$ carries $\mathcal{N}^\perp$ onto $(S \mathcal{N})^\perp$ as desired. ■

It is desirable to arrange it so that only perturbations of a fixed nest $\mathcal{N}$ need be considered. Moreover, it would help if these perturbations always commute. To this end, one arranges that the perturbations consist of sum of finite atoms and sub projections of infinite atoms in a fixed mass.

17.19 Lemma. Let $\mathcal{N}$ be a nest. Extend $\mathcal{N}^\sigma$ to a von Neumann algebra $\mathcal{M}$ whose restriction to each infinite atom is an atomic masa, but agrees with $\mathcal{N}^\sigma$ on the complement of the infinite atoms. Let $S$ be an invertible operator such that $Q \tau (S \mathcal{N}) = Q \tau (\mathcal{N})$. Then there is an invertible, compact perturbation $S_0$ of $S$ and two finite dimensional subspaces $F$ and $G$ with $P(F)$ and $P(G)$ in $\mathcal{M}$ such that $S_0 \mathcal{M}^\perp = \mathcal{N}^\perp$.

Proof. By Theorem 12.8, there are finite dimensional subspaces $F_1$ and $G_1$ with $P(F_i)$ in $(S \mathcal{N})^\perp$ and $P(G_i)$ in $\mathcal{N}^\perp$ and a compact operator $K$ so that $(I+K)(S \mathcal{N})^\perp = \mathcal{N}^\perp$. By the previous lemma, there is a subspace $F_2$ with $P(F_2)$ in $\mathcal{N}^\perp$ and a compact perturbation $S_1$ of $S$ so that $S_1 \mathcal{N}^\perp = (S \mathcal{N})^\perp$. Thus $(I+K)S_1 \mathcal{N}^\perp = \mathcal{N}^\perp$. Let $S_2 = (I+K)S_1$. It remains to modify $F_2$, $G_1$ and $S_2$ so that the subspaces have projections in $\mathcal{M}$ instead of just $\mathcal{N}^\perp$.

Let $H_1, \ldots, H_n$ be the atoms of $\mathcal{N}$ such that $H_j P(G_1) \neq 0$ and let $H = \sum_{j=1}^n H_j$. Let $E_1, \ldots, E_m$ be the atoms $E$ of $\mathcal{N}$ such that either $P(F_2) E \neq 0$ or $\theta_{S_0}(E) \leq H$. Let $F$ be the sum of the finite dimensional spaces $E_i \mathcal{N}$, $1 \leq i \leq n'$, together with subspace $M_i$ of the infinite atoms $E_i \mathcal{N}$, $n' < i \leq n$, so that $P(M_i)$ belongs to $\mathcal{M}$ and $\dim M_i = \dim (F_2 \wedge E_i \mathcal{N})$. Let $U$ be a unitary of the form $I + \sum_{i=n'+1}^n E_i K_i E_i$ where $K_1$ is finite rank, and $U M_i = F_2 \wedge E_i \mathcal{N}$ for each infinite atom. Similarly, if $H_j$ is an infinite atom, choose a subspace $L_j$ so that $P(L_j)$ belongs to $\mathcal{M}$ and $\dim L_j = \dim (G_1 \wedge H_j \mathcal{N})$. Let $V$ be a unitary of the form $I + \sum_{j=1}^n H_j K_2 H_j$ where $K_2$ is finite rank and $V L_j = G_1 \wedge H_j \mathcal{N}$. Let $F_3 = U^* F_2$, $G_2 = V^* G_1$, and $S_3 = V^* S_2 U$. Note that $S_3$ takes $\mathcal{N}^\perp$ onto $\mathcal{N}^\perp$. Now $P(F)$ is the sum of atoms of $\mathcal{M}^\perp$. Thus $\theta_{S_3}(P(F)) = P(G)$ is the sum of atoms of $\mathcal{M}^\perp$ which includes all finite rank atoms $H_j$, as well as $\theta_{S_3}(E_i P(F_2) L_i)$ when $E_i$ is infinite. So $G$ is the sum of
atoms of \( \mathcal{M} \) together with the \( L_j \) for infinite atoms. Hence \( F \) and \( G \) have the desired form.

Set \( S_0 = P(G)S_3P(F) + P(G)^{\perp}S_3P(F)^{\perp} \). It must be shown that \( S_0 \) is invertible. The atoms comprising \( F \) in \( \mathcal{M}^{\mathcal{F}} \) split \( \mathcal{F} \) into intervals \( A_1,...,A_k \) where the odd intervals belong to \( F \), and the even intervals to \( F^{\perp} \). Likewise, \( \mathcal{F}^{\mathcal{G}} \) is split into intervals \( B_1,...,B_k \). The operators \( S_3 \) and \( S_3^{-1} \) written as operator matrix from \( \sum \oplus A_i \) to \( \sum \oplus B_i \) and back are both upper triangular. Hence their diagonal entries are invertible. From this it follows that \( P(G)S_3P(F) \) and \( P(G)^{\perp}S_3P(F)^{\perp} \) are invertible (and upper triangular) as operators in \( B(F,G) \) and \( B(F^{\perp},G^{\perp}) \) respectively. So \( S_0 \) is invertible. A review of the definition of \( S_0 \) shows that \( S-S_0 \) is compact. It is clear that \( S_0\mathcal{M} = \mathcal{M}^{\mathcal{G}} \).

At this stage, one can prove the analogue of Corollary 17.15.

**17.20 Theorem.** Let \( \alpha \) be an automorphism of \( Q\mathcal{T}(\mathcal{M}) \) such that \( \|\alpha-\text{id}\| < 1 \). Then \( \alpha \) is inner via \( S \) in \( Q\mathcal{T}(\mathcal{M})^{-1} \) such that \( \|S-I\| \leq 2\|\alpha-\text{id}\| \).

**Proof.** By Theorem 17.7, \( \alpha = \text{Ad} S \) for some invertible operator \( S \). Normalize \( S \) so that \( \|S\| = 1 \). Let \( \epsilon = \|\alpha-\text{id}\| \). For each \( K \) in \( \mathcal{K} \),

\[
\|SK-KS\| = \|(\alpha(K)-K)S\| \leq \|\alpha-\text{id}\| \|K\| \|S\| = \epsilon\|K\|
\]

Thus by the weak* continuity of \( \delta_S \), \( \|\delta_S\| \leq \epsilon \). By Theorem 9.6, there is a scalar \( \lambda \) so that \( \|S-\lambda I\| \leq \epsilon \). Since \( \|S\| = 1 \), \( |1-\lambda| \leq \|S-\lambda I\| \). Hence \( \|S-I\| \leq 2\epsilon \). It remains to show that \( S \) belongs to \( Q\mathcal{T}(\mathcal{M})^{-1} \).

Now \( Q\mathcal{T}(\mathcal{N}) = \alpha(Q\mathcal{T}(\mathcal{M})) = Q\mathcal{T}(S\mathcal{M}) \). So by Lemma 17.19, there is an invertible, compact perturbation \( S_0 \) of \( S \) so that \( S_0\mathcal{M}^{\mathcal{F}} = \mathcal{M}^{\mathcal{G}} \), and \( P(F) \) and \( P(G) \) are finite rank projections in \( \mathcal{M} \) (as described in that lemma). Now \( S_0S_0^{-1}I = K \) is compact, so \( \alpha_0 = \text{Ad} S_0 \) factors as \( \alpha_0 = \text{Ad}(I+K)\alpha \). Let \( \theta = \theta_{S_0} \) be the order isomorphism of \( \mathcal{M}^{\mathcal{F}} \) onto \( \mathcal{M}^{\mathcal{G}} \) induced by \( S_0 \), and consider it extended to all intervals. By Theorem 8.3, there is an expectation \( \Phi \) of \( B(\mathcal{M}) \) onto \( \mathcal{M} \). For each interval \( E \), \( \alpha_0(E) \) is an idempotent with range \( \theta(E) \). So \( \theta(E) = \Phi \alpha_0(E) \). Since \( \Phi \) is contractive and \( \Phi(E) = E \),

\[
\|\theta(E)-E\| \leq \|\alpha_0(E)-E\| \leq \|(\alpha_0-\text{id})(E)\| + \|\alpha-\text{id}\| \leq \epsilon.
\]

Let \( (E_n) \) be any family of pairwise orthogonal intervals. Then since \( K \) is compact, \( \|(\alpha_0-\alpha)(E_n)\| = \|\text{Ad}(I+K)\alpha(E_n)\| < 1-\epsilon \) for all except finitely many \( n \). Now \( \theta(E_n) \) and \( E_n \) belong to \( \mathcal{M} \) and thus commute; as \( \|\theta(E_n)-E_n\| \leq 1 \), then \( \theta(E_n) = E_n \) except finitely often. Also,

\[
\|\theta(E)-E\| \leq \|\alpha-\text{id}\| < 1
\]

so \( \theta(E) - E \) is compact and hence finite rank. In particular, \( \theta(A) = A \) for all but a finite set of atoms \( \{A_1,...,A_n\} \). Let \( Q = \sqrt{\sum_{i=1}^{n}(A_i-\theta(A_i))^2} \), the least
projection in \( \mathcal{M} \) dominating \(|A_i - \theta(A_i)|\) for all \( i \). Then \( Q \) is finite rank. Let \( E \) be an interval of \( \mathcal{N}^F \), and write \( \theta(E) - E = B_1 - B_2 \) where \( B_i \) are pairwise orthogonal projections on \( \mathcal{M} \). As \( B_i \) are finite rank, they are contained in the atomic part of \( \mathcal{N}^F \) or \( \mathcal{N}^G \). If \( A \) is an atom of \( \mathcal{N}^F \) such that \( AB_2 \neq 0 \), then \( \theta(A) \leq \theta(E) \), whence \( AB_2 = (A - \theta(A))B_2 \leq QB_2 \). Similarly, if \( A \) is an atom such that \( \theta(A)B_1 \neq 0 \), then \( A \leq E \) so \( AB_1 = 0 \). Thus \( \theta(A)B_2 = (\theta(A) - A)B_2 \leq QB_2 \). It follows that \( Q \perp \theta(E) = Q \perp E \) for every interval. In particular, if \( N \) belongs to \( \mathcal{N}^F \),

\[
Q^\perp N = Q^\perp \theta(P(N))N = Q^\perp S_0 N.
\]

So \( Q^\perp S_0 \) belongs to \( T(\mathcal{N}^F) \). Likewise \( Q^\perp S_0^{-1} \) belongs to \( T(\mathcal{N}^G) \). As \( S \) and \( S^{-1} \) are compact perturbations of these operators, they both belong to \( Q T(\mathcal{N}) \).

17.21. Let \( S, F, G, S_0, \mathcal{N}^F, \) and \( \mathcal{N}^G \) be as in Lemma 17.19. Let \( F_0 \) and \( G_0 \) be the sums of finite atoms dominated by \( F \) and \( G \) respectively. Now \( S_0 \) induces an automorphism \( \theta S_0 \) of \( \mathcal{N}^F \) onto \( \mathcal{N}^G \) which extends naturally to intervals. In particular, each infinite atom of \( \mathcal{N}^F \) is taken to an infinite atom of \( \mathcal{N}^G \). These infinite atoms are finite rank perturbations of atoms of \( \mathcal{N} \). Let \( \mathcal{N}_{F_0} \) (and \( \mathcal{N}_{G_0} \)) denote the restriction of \( \mathcal{N} \) to \( F_0 \perp \mathcal{N} \). Then \( \theta S_0 \) induces an element \( \tilde{\theta} = \tilde{\theta} S_0 \) in \( ISOM(\mathcal{N}_{F_0}, \mathcal{N}_{G_0}) \) by identifying each infinite atom in \( \mathcal{N} \) with the corresponding infinite atom of \( \mathcal{N}_{F_0} \) (and \( \mathcal{N}_{G_0} \)). This isomorphism \( \tilde{\theta} \) is not uniquely determined by \( S \). For example, if \( E = \sum E_i \) is a sum of finite atoms of \( \mathcal{N}_{F_0} \), let \( H = \tilde{\theta}(E) = \sum \tilde{\theta}(E_i) \) be the corresponding sum of atoms in \( \mathcal{N}_{G_0} \). Set \( S_1 = ES_0H + E^\perp S_0H^\perp \). One argues as in the last paragraph of the proof of Lemma 17.19 that \( S_1 \) is invertible and \( S_1 \) takes \( \mathcal{N}^F + E \) to \( \mathcal{N}^G + H \). Moreover, \( \theta S_1 \) in \( ISOM(\mathcal{N}_{F_0+E}, \mathcal{N}_{G_0+H}) \) is just the restriction of \( \tilde{\theta} S_0 \) to \( \mathcal{N}_{F_0+E} \).

This discussion leads to the following group of "almost automorphisms" of \( \mathcal{N} \). Let \( P(\mathcal{N}) \) denote the set of pairs \((F,G)\) of sums of atoms of \( \mathcal{N} \), with the further stipulation in the case that \( \mathcal{N} \) has no infinite rank atoms that \( \text{rank} F = \text{rank} G \). Let \( \mathcal{N}_F = \mathcal{N} \mid F^\perp \) and let \( ISOM(\mathcal{N}_F, \mathcal{N}_G) \) denote the dimension preserving isomorphisms of \( \mathcal{N}_F \) onto \( \mathcal{N}_G \). If \( \theta \) is such a map and \( E = \sum E_i \) is the sum of finite rank atoms of \( \mathcal{N}_F \), let \( H = \sum \theta(E_i) \) and define \( \theta_E \) in \( ISOM(\mathcal{N}_{F+E}, \mathcal{N}_{G+H}) \) by restriction. Let \( G \) denote the union \( \bigcup \{ ISOM(\mathcal{N}_F, \mathcal{N}_G); (F,G) \in P(\mathcal{N}) \} \). Put an equivalence relation on \( G \) by \( \theta \sim \eta \) if there are sums of atoms \( E \) and \( F \) so that \( \theta_E = \eta_F \). Let \( [\theta] \) denote the equivalence class of \( \theta \) in \( G / \sim \).
Isomorphisms

Define an associative multiplication on $\mathcal{G}/\sim$ as follows: Given $\theta$ in $ISO(\mathcal{M}_F, \mathcal{M}_G)$ and $\eta$ in $ISO(\mathcal{M}_G, \mathcal{M}_H)$, let $A = \theta^{-1}(G \perp E)$ and $B = E \perp G$. Then $\theta_A$ belongs to $ISO(\mathcal{M}_{F+A}, \mathcal{M}_G \perp E)$ and $\mathcal{N}_B$ belongs to $ISO(\mathcal{N}_{G \perp E}, \mathcal{N}_{H+\eta(E)})$. So $\eta_B \theta_A$ is defined in $ISO(\mathcal{M}_{F+A}, \mathcal{M}_{H+\eta(E)})$. Let $[\eta] [\theta] = [\eta_B \theta_A]$. It is left to the reader to verify that this makes $\mathcal{G}/\sim$ a group with identity element $[id]$, and the relation $[\theta]^{-1} = [\theta^{-1}]$. This group will be denoted by $a-Aut(\mathcal{N})$.

Define a map from $Aut_Q T(\mathcal{N})$ into $a-Aut \mathcal{N}$ as follows. For each automorphism $\alpha = Ad S$, use Lemma 17.19 to obtain a compact perturbation $S_0$ such that $\theta S_0$ belongs to $ISO(\mathcal{N}^F, \mathcal{N}^G)$. As above, form $\theta S_0$. Define $\Theta(\alpha) = [\theta S_0]$.

17.22 Theorem. The map $\Theta$ is a well defined homomorphism of $Aut_Q T(\mathcal{N})$ onto $a-Aut \mathcal{N}$ with kernel $Inn Q T(\mathcal{N})$. Hence $Out Q T(\mathcal{N})$ is naturally isomorphic to $a-Aut \mathcal{N}$.

Proof. First show that $\Theta$ is well defined. Let $\alpha = Ad S$ belong to $Aut_Q T(\mathcal{N})$ and let $S_0$ and $S_1$ be two invertible compact perturbations of $S$ which implement isomorphisms $\theta_i$ of $F_i^o$ onto $G_i$, $i = 0, 1$. Let $F_i^o(G_i)$ denote the sum of finite atoms dominated by $F_i^o (G_i)$ and let $\bar{\theta}_i$ be the induced map in $ISO(\mathcal{M}_{F_i^o}, \mathcal{N}_{G_i})$. Let $\alpha_i = Ad S_i$ and $K = S_1 S_0^{-1} - I$. Then $\alpha_1 = (Ad I + K) \alpha_0$. For any operator $A$ in $Q T(\mathcal{N})$, $\alpha_1(A) - \alpha_0(A)$ is compact and hence $\Phi \alpha_1(A) - \Phi \alpha_0(A)$ is compact (where $\Phi$ is the expectation onto $\mathcal{N}$). In particular, each infinite atom of $\mathcal{N}$ is taken to the same infinite atom by both $\theta_i$, $i = 0, 1$. Also, if $E$ is an interval of $\mathcal{N}$ orthogonal to $F_0 + F_1$ then

$$\bar{\theta}_1(E) - \bar{\theta}_0(E) = \Phi \alpha_1(E) - \Phi \alpha_0(E) = \Phi(Ad (I + K) - id) \alpha_0(E)$$

is compact; and thus is of the form $A_1 - A_0$ where $A_1$ and $A_0$ are finite sums of finite rank atoms of $\mathcal{N}$. In particular, this difference has norm zero or one. The compactness of $K$ ensures that if $\{E_n\}$ are pairwise orthogonal intervals, then $\bar{\theta}_i(E_n) = \bar{\theta}_0(E_n)$ except finitely often. Let $\{E_{1i},...,E_{ni}\}$ be the atoms such that $\bar{\theta}_i(E_{ni}) \neq \bar{\theta}_0(E_{ni})$, and one may suppose that the first $m$ are finite rank. Let $H_i = F_1^o + \bigvee_{i=1}^m E_{ni}$. It will be shown that $\bar{\theta}_{0H_0} = \bar{\theta}_{1H_1}$. Let $N$ belong to $\mathcal{N}$ and consider $H_{\perp} P(N)$ where $H = H_0 \perp H_1$. Now $\bar{\theta}_1(H_{\perp} P(N)) - \bar{\theta}_0(H_{\perp} P(N)) = A_1 - A_0$ as above. But as in the proof of Theorem 17.20, it follows that $A_0 = A_1 = 0$. For if $E$ is an atom of $\mathcal{N}$ and $E \leq A_0$, then $E \leq \bar{\theta}_0(H_{\perp} P(N))$ so $E' = \bar{\theta}_0^{-1}(E) \leq H_{\perp} P(N)$; but $E \bar{\theta}_1(H_{\perp} P(N)) = 0$ so $\bar{\theta}_1(E)$ is orthogonal to $H_{\perp} P(N)$. This means $E' \leq H$, which is absurd. Hence it has been shows that $[\theta_0] = [\theta_1]$, and $\Theta$ is well defined.
It is readily apparent that $\Theta$ is a homomorphism. For let $\alpha_i = Ad S_i$, $i=1,2$, be automorphisms. Let $S'_i$ be compact perturbations implementing $\tilde{\theta}_i$ in $ISO(\mathcal{H}_{F_i},\mathcal{H}_G)$. Choose sums of atoms $H_1$ and $H_2$ so that $\tilde{\theta} = \tilde{\theta}_1 H_1 \tilde{\theta}_2 H_2$ is defined. By Remark 17.21, there is a compact perturbation $S''_i = (H_2 S'_i H_1^* + H_1 S'_i H_2^*)$ which implements $\tilde{\theta}_i H_i$. So $S''_1 S''_2$ is an invertible compact perturbation of $S_1 S_2$. It is clear that $S''_1 S''_2$ implements $\tilde{\theta}$. So $\Theta(\alpha_1) \Theta(\alpha_2) = \Theta(\alpha_1 \alpha_2)$.

Suppose $\Theta(\alpha) = [id]$. Then $\alpha = Ad S$ and $S$ has a compact perturbation $S_0$ mapping $\mathcal{K}$ onto $\mathcal{K}$ such that $S_0(N \vee F) = N \vee G$ for every $N$ in $\mathcal{K}$. So $S$ and $S^{-1}$ belong to $Q T(\mathcal{K})$, and thus $\alpha$ is inner.

Conversely, suppose $S$ belongs to $Q T(\mathcal{K})^{-1}$, and $S_0$ is an invertible compact perturbation mapping $\mathcal{K}$ onto $\mathcal{K}$. Now $S_0$ is bounded below by some $\epsilon > 0$, so for each $N$ in $\mathcal{K}$, $S_0 \phi_1(N)$ contains $b_1(\theta(N))$. Write $S_0 = T + K$ where $T$ belongs to $T(\mathcal{K})$ and $K$ is compact. Then $P(N) = S_0 \phi_1(N)$ contains $b_1(P(N)\phi_1(N))$, and thus this is finite rank. By considering $S_0^{-1}$ as well, we conclude that $P(\theta(N)) = P(N)$ is finite rank. Hence $\theta(E) = E$ is finite rank for every interval, and hence is of the form $A_1 \cdots A_2$ where $A_i$ are sums of finite atoms of $\mathcal{K}$, and subprojections of $G$ and $F$ respectively. Now if $(E_n, n \geq 1)$ are the finite rank atoms of $\mathcal{K}$ orthogonal to $F$, then $\theta(E_n) > E_n$ in the order of $\mathcal{K}$ means that $\theta(E_n) K E_n$ is bounded below by $\epsilon$ on $E_n$. So this occurs only finitely often. So $\theta(E) = E$ except for a finite set $E_1, \ldots, E_n$. If $E$ is an infinite atom, $\theta(E)$ is an infinite atom in $\mathcal{K}$ and $E - \theta(E)$ is compact; so they correspond to the same atom of $\mathcal{K}$. Furthermore, $E = \theta(E)$ except those finitely many which meet $F$ or $G$.

Finally, we argue as before to show that if $F$ is an interval orthogonal to the finitely many atoms for which $\theta(E) \neq E$, then $\theta(F) = F$. Hence $[\theta] = [id]$. Thus $ker \Theta = Inn Q T(\mathcal{K})$.

Now we show that $\Theta$ is surjective. Let $\theta$ in $ISO(\mathcal{H}_{F_i},\mathcal{H}_G)$ representative of $[\theta]$. By the Similarity Theorem 13.20, there is an invertible operator $S$ in $B(F \vee G)$ which implements $\theta$. If $rank F = rank G$, $S$ can be extended to an invertible operator in $B(\mathcal{H})$ of the form $S' = G \vee F \vee G$ where $U$ is unitary. Clearly, $Ad S$ takes $T(\mathcal{K})$ onto $T(\mathcal{K})$, hence $Ad S$ is an automorphism of $Q T(\mathcal{K})$. Also, it is apparent that $\Theta(Ad S) = [\theta]$. If $rank F \neq rank G$, then $\mathcal{N}$ has an infinite atom $A$. Suppose that $rank F < rank G$. Let $E$ be a projection in $\mathcal{K}$ with $E \leq A$ and $rank E + rank F = rank G$. Let $U$ be a unitary operator on $\mathcal{H}$ which carries $(E+F)\mathcal{H}$ onto $G\mathcal{H}$, takes $AE \mathcal{H}$ onto $A\mathcal{H}$, and is the identity on $(A+F)\mathcal{H}$. Let $S' = U(F \vee G \vee SF \vee)$. This is invertible by construction, and $S'(F \vee E)\mathcal{H} = G\mathcal{H}$. If $N$ belongs to $\mathcal{K}$, then

$$S'(N \vee F \vee E) = US'N \vee G = U\theta(N) \vee G = \theta(N) \vee G.$$

So $\Theta(Ad S') = [\theta]$. If $rank F > rank G$, obtain $S'$ as above so that $\Theta(Ad S') = [\theta^{-1}]$. Then $\Theta(Ad S'^{-1}) = [\theta]$.
The map $\Theta$ is “natural” in the sense made clear in the previous paragraph. Namely, $\alpha+\text{Inn}Q \cong (\mathcal{N})$ contains a representative $\text{Ad}S$ which implements a representative $\theta$ in $\Theta(\alpha)$.

\textbf{17.23 Corollary.} Let $\mathcal{N}$ be a continuous nest. Then $\text{Out}Q \cong (\mathcal{N})$ is isomorphic to $\text{Homeo}_0[0,1]$, the order preserving homeomorphisms of $[0,1]$.

\textbf{Proof.} As $\mathcal{N}$ has no atoms, $\text{aAut} \mathcal{N} = \text{Aut} \mathcal{N}$. As $\mathcal{N}$ is order isomorphic to $[0,1]$, the result follows.

\textbf{17.24 Corollary.} Let $\mathcal{N}$ be a nest of order type $\omega = \mathbb{N} \cup \{\infty\}$, and let the atoms by $\{A_n, k \geq 1\}$. Then $\text{Out}Q \cong (\mathcal{N}) = 0$ or $\mathbb{Z}$. The latter occurs if and only if there is a finite, non-zero number of infinite rank atoms and rank $A_k$ is eventually periodic.

\textbf{Proof.} Let $E$ (and $F$) be a sum of $e$ (and $f$) finite atoms of $\mathcal{N}$. Then $\mathcal{N}_E$ and $\mathcal{N}_F$ are nests of order type $\omega$. So $\text{ISO}(\mathcal{N}_E, \mathcal{N}_F)$ is either empty, or has exactly one element $\theta$ taking the $n$-th atom of $\mathcal{N}_E$ to the $n$-th atom of $\mathcal{N}_F$. In the latter case, this implies that $\text{rank}(A_{n+k}) = \text{rank}(A_{n+k})$ for $n$ sufficiently large. If $e = f$, this is equivalent to $[\text{id}]$. But if $k = e - f \neq 0$, then there is an integer $n_k$ so that $\text{rank}(A_{n+k}) = \text{rank}(A_n)$ for all $n \geq n_0$. In this case the span of the first $n_0+k$ atoms is sent onto the first $n_0$ atoms. This can only occur if this span is infinite dimensional. So there are infinite atoms. The nests $\mathcal{N}_E$ and $\mathcal{N}_F$ have exactly the same infinite atoms in exactly the same order. So they must be mapped identically onto themselves ($\theta(A) = A$ for every infinite atom). Thus if $k \neq 0$, there are only finitely many infinite atoms. Conversely suppose $\mathcal{N}$ has a finite non-zero number of infinite atoms, including $A_j$ say, and that there are positive integers $n_0$ and $k_0$ so that $\text{rank}(A_{n+k_0}) = \text{rank}(A_n)$ for all $n \geq n_0$. Also suppose that $k_0$ is minimal. Let $E$ be the sum of all finite atoms $A_i$ with $i < n_0+k_0$, and let $F$ be the sum of the finite atoms $A_i$ with $i < n_0$. Define a map $\theta_0$ taking each infinite atom to itself and $\theta_0(A_{n+k}) = A_n$ for $n \geq n_0$. This is an element of $\text{ISO}(\mathcal{N}_E, \mathcal{N}_F)$. If $[\theta]$ is any element of $\text{aAut} \mathcal{N}$, then the integer $k = e - f$ is a multiple $k_0\theta$ of $k_0$. It follows that $[\theta] = [\theta_0]^k$. So $\text{aAut} \mathcal{N}$ is isomorphic to $\mathbb{Z}$.

\textbf{Notes and Remarks.}

Theorem 17.1 on unitarizing groups is due to Dixmier [2]. Corollary 17.3 was proven independently by Werner [1] who used it to show that commuting spectral operators are similar to commuting normal operators. (See Dunford and Schwartz [1], volume 3). Theorem 17.4 is from Dixmier [4] Chapter III, Part 3 § 2. Theorem 17.12 and Corollary 17.13 are due to Ringrose [4]. Theorem 17.5 is a generalization of this work due to Gilfeather and Moore [1]. Theorem 17.7 is essentially due to Rickart [1].
2.5.9. The applications of the Similarity Theorem, Corollaries 17.14 and 17.15, are due to Davidson and Wagner [1]. Lemmas 17.16 and 17.17 are taken from the ideas in Apostol-Gilfeather [1] and Apostol-Davidson [1]. Theorem 17.20 is due to Wagner [2], and Theorem 17.22 is due to Davidson-Wagner [1]. The approach taken here to these results is a modified version of the latter paper. Partial results on this subject are also contained in Wagner’s thesis [1].

One can also study isomorphisms between the quotient algebras $Q T(\mathcal{N})/K$. In this case, there are no finite rank operators, so the analysis is more subtle. It is shown in Apostol-Gilfeather [1] and Apostol-Davidson [1] that any two such algebras which are isomorphic are unitarily equivalent (in the Calkin algebra). For example, suppose $\mathcal{N}$ and $\mathcal{M}$ have order type $\omega = \mathbb{N} \cup \{\infty\}$ with atoms of rank $\{d_n, n \geq 1\}$ and $\{e_n, n \geq 1\}$ respectively. Then $Q T(\mathcal{N})/K$ and $Q T(\mathcal{M})/K$ are isomorphic if and only if there are integers $n_0$ and $m_0$ so that $d_{m_0+k} = d_{m_0+k}$ for $k \geq 1$.

However, it is not known even in this special case whether all such isomorphisms are spatially implemented.

**Exercises.**

17.1 Let $\mathcal{A}$ be a $C^*$-algebra which is generated as a $C^*$-algebra by an amenable subgroup $G$ of the unitary group. Show that every bounded representation of $\mathcal{A}$ is similar to a unitary representation.

17.2 (a) If $\mathcal{N}$ is a nest of order type $\omega = \mathbb{N} \cup \{\infty\}$, show that every automorphism of $T(\mathcal{N})$ is inner.

(b) If $\mathcal{N}$ is a nest of order type $\omega^+ \omega = \{-\infty\} \cup \mathbb{Z} \cup \{\infty\}$, show that Out $T(\mathcal{N})$ is 0 or $\mathbb{Z}$. When is it $\mathbb{Z}$?

17.3 (Wagner) Classify Out $Q T(\mathcal{N})$ when $\mathcal{N}$ has order type $\omega^+ \omega$.

There are five possibilities for the infinite rank atoms: (φ) none; (F) finite, non-zero; (N) countably many, order type $\omega$; (N*) countably many, order type $\omega^*$; and (Z) countably many, order type $\omega^+ \omega$.

There are four possibilities for partial periodicity of $d_n = \text{rank} A_n$: (P⁺), there are positive integers $n_0$ and $k_0$ so that $d_{n+k_0} = d_n$ for $n \geq n_0$; (P⁻), there are negative integers $m_0$ and $l_0$ so that $d_{m+l_0} = d_m$ for $m \leq m_0$; (DP) = $P_+ \cup P_-$; and (NP) neither $P_+$ nor $P_-$. Show that Out $Q T(\mathcal{N})$ is given by the following chart:

<table>
<thead>
<tr>
<th>$\phi$</th>
<th>$F$</th>
<th>$N$</th>
<th>$N^*$</th>
<th>$Z$</th>
</tr>
</thead>
<tbody>
<tr>
<td>NP</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>P⁺</td>
<td>0</td>
<td>$\mathbb{Z}$</td>
<td>0</td>
<td>$\mathbb{Z}$</td>
</tr>
<tr>
<td>P⁻</td>
<td>0</td>
<td>$\mathbb{Z}$</td>
<td>$\mathbb{Z}$</td>
<td>0</td>
</tr>
<tr>
<td>DP</td>
<td>$\mathbb{Z}$</td>
<td>$\mathbb{Z}$ $\oplus$</td>
<td>$\mathbb{Z}$</td>
<td>$\mathbb{Z}$ $\oplus$</td>
</tr>
</tbody>
</table>
17.4 (a) Show that every automorphism of \( T(\mathcal{N}) \) extends uniquely to an automorphism \( Q T(\mathcal{N}) \). Thus there is an injection \( i: \text{Aut} T(\mathcal{N}) \rightarrow \text{Aut} Q T(\mathcal{N}) \).

(b) Show that \( i^{-1}(\text{Inn} Q T(\mathcal{N})) = \text{Inn} T(\mathcal{N}) \). Hence \( \text{Out} T(\mathcal{N}) \) imbeds as a subgroup of \( \text{Aut} Q T(\mathcal{N}) \).

(c) Show that the map \( j: \text{Aut}(\mathcal{N}) \rightarrow a - \text{Aut} \mathcal{N} \) given by \( j(\theta) = [\theta] \) is an injection, and that this diagram commutes:

\[
\begin{array}{ccc}
\text{Aut} T(\mathcal{N}) & \xrightarrow{i} & \text{Aut} Q T(\mathcal{N}) \\
\downarrow \pi & & \downarrow \pi \\
\text{Aut} \mathcal{N} & \xrightarrow{j} & a - \text{Aut} \mathcal{N}
\end{array}
\]

17.5 Let \( \mathcal{N} \) be a nest and let \( A \) be an invertible element of \( Q T(\mathcal{N}) \).

Show that \( A \) factors as \( A = (I + K)V \) where \( K \) is compact, \( T \) is an invertible element of \( T(\mathcal{N}) \), \( E_1, \ldots, E_n \) are infinite rank atoms with \( E = \sum_{i=1}^{n} E_i \), and \( V \) is a unitary operator of the form \( V = E_1 + E_1 V E \) such that \( VE_i V^* \) belongs to \( \mathcal{N} \) and \( VE_i - E_i V \) is compact, \( 1 \leq i \leq n \).

The converse is easy.

17.6 (Gilfeather-Moore)

(a) Let \( \mathcal{A}_4 \) consist of all operators of the form

\[
\begin{bmatrix}
    a & b & 0 & h \\
    0 & c & 0 & 0 \\
    0 & d & e & f \\
    0 & 0 & 0 & g
\end{bmatrix}
\]

Show that this is a CSL algebra. Define a map \( \rho \) by leaving all coordinates the same except the \((1,4)\) entry, which is replaced by \(-h\). Show that \( \rho \) is an automorphism which does not preserve rank. Hence \( \rho \) is not spatial.

(b) Let \( \mathcal{A}_6 \) be the 6×6 analogue consisting of matrices

\[
\begin{bmatrix}
    * & * & * \\
    * & * & * \\
    * & * & * \\
    * & * & * \\
    * & * & * \\
    * & * & *
\end{bmatrix}
\]

Again, define \( \rho \) by switching the sign of the \((1,6)\) entry. Show that \( \rho \) is an automorphism. Show that \( \rho \) preserves rank one operators but not rank two operators.
(c) Let \( \mathcal{A}_\infty \) denote the algebra of operators of the form
\[
\begin{bmatrix}
  * & * & * & * & * & * \\
  * & * & * & * & * & * \\
  * & * & * & * & * & * \\
  * & * & * & * & * & * \\
  * & * & * & * & * & * \\
  * & * & * & * & * & * \\
\end{bmatrix}
\]
Let \( T = \text{diag}(1,2,3,...) \) and define \( \rho \) by \( \rho(A) = TAT^{-1} \). Verify that \( \rho \) is a continuous automorphism which is not spatial.

17.7 (Gilfeather-Moore) Let \( L \) be a CSL and let \( \beta \) be an automorphism of \( \text{Alg} L \) such that \( \beta(M) = \text{id} \) for some masa \( M \).

(a) For each projection \( E \) in \( M \), let \( \beta_E(T) = \beta(T)E \). Let \( \mathcal{E} \) be the set of projections such that \( \beta_E \) is continuous. Show that \( \mathcal{E} \) is closed under span.

(b) Use the Uniform Boundedness Principle to prove that \( \{\|\beta_E\| : E \in \mathcal{E}\} \) is bounded. Hence show that \( \mathcal{E} \) is closed under countable unions. Hence deduce that \( \mathcal{E} \) has a greatest element \( E_\mathcal{E} \).

(c) Show that \( E_\mathcal{E}^\perp \) is finite dimensional. Hint: If \( E_\mathcal{E}^\perp \) can be split into a set \( \{E_n : n \geq 1\} \) of pairwise orthogonal projections in \( M \), build an operator \( A = \sum A_n E_n \) such that \( \beta(A) \) is not bounded.

(d) Similarly, find a maximal projection \( E_1 \) in \( M \) so that \( \beta E_1(T) = E_1 \beta(T) \) is continuous.

(e) Show that the map \( \alpha(T) = E_1^\perp \beta(T) E_\mathcal{E}^\perp \) is continuous. Hence deduce that \( \beta \) is continuous.

(f) Show that every algebraic isomorphism between CSL algebras is continuous.
18. Perturbations of Operator Algebras

Perturbation results strive to show that two subalgebras of a larger algebra with "close" unit balls are spatially related (unitary equivalence, similarity, etc.). Such results exist for nest algebras and for certain classes of von Neumann algebras. Here we will deal only with the abelian and abelian commutant case. There is a close connection between perturbation results and results on cohomology and derivations. These will be dealt with in the next chapter.

The distance between two subspaces $M$ and $N$ of a Banach space will be given by the Hausdorff distance between their unit balls $b_1(M)$ and $b_1(N)$:

$$d(M,N) = d_H(b_1(M),b_1(N))$$

$$\quad = \max \left\{ \sup_{m \in b_1(M) \cap b_1(N)} \inf_{n \in b_1(N)} \| n - m \|, \sup_{n \in b_1(N) \cap b_1(M)} \inf_{m \in b_1(M)} \| n - m \| \right\} .$$

The first theorem deals with more general reflexive algebras. Then we specialize to nest algebras.

18.1 Lemma. Let $B$ be a unital Banach algebra. For each $B$ in $b_1(B)$, there is a idempotent $F$ satisfying $\|B-F\| \leq 3\|B-B^2\|$. When $\|B-B^2\| \leq 1/8$, one can achieve $\|B-F\| \leq 5\|B-B^2\|$.

Proof. If $\|B-B^2\| > 1/8$, take $F = 0$. Suppose $\|B-B^2\| = \epsilon \leq 1/8$. Define

$$T = [I - 4(B-B^2)]^{-1} = I + \sum_{n=1}^{\infty} \frac{2n}{n} (B-B^2)^n .$$

This series converges absolutely, and

$$\|T-I\| \leq \sum_{n=1}^{\infty} \frac{2n}{n} \epsilon^n = (1 - 4\epsilon)^{-1} - 1$$

$$= \frac{4\epsilon}{1-4\epsilon + \sqrt{1-4\epsilon}} \leq \frac{4\epsilon}{1/2 + 1/\sqrt{2}} < \frac{10}{3} \epsilon .$$

Furthermore, $T$ commutes with $B$ and $(I-2B)^2T^2 = I$. Define $F$ by the identity $I-2F = (1-2B)T$. Squaring yields $F = F^2$. Moreover,
\[ \| F - B \| = \frac{1}{2} \| (I - 2B) - (I - 2F) \| \]
\[ = \frac{1}{2} \| (I - 2B)(I - T) \| < \frac{1}{2} \cdot 3 \cdot \frac{10}{3} \epsilon = 5 \epsilon . \]

18.2 Theorem. Let \( \mathcal{A} = \text{Alg} L \) be a reflexive algebra with a commutative subspace lattice \( L \). Let \( B \) be a norm closed subalgebra of \( B (\mathcal{H}) \) such that \( d(\mathcal{A}, B) = \delta < 1/20 \). Then there is a complete lattice isomorphism \( \theta \) of \( \mathcal{M} = \text{Lat} B \) onto \( L \) such that \( \| \theta - \text{id} \| \leq 2 \delta \).

Proof. Fix \( M \) in \( \mathcal{M} \) and let \( P = P(M) \). The algebra \( \mathcal{A} \) contains the von Neumann algebra \( \mathcal{A} \cap \mathcal{A}^* = L' \) which has abelian commutant \( L'' \). For each \( A \) in \( b_1(L) \), pick \( B \) and \( C \) in \( b_1(B) \) such that \( \| A - B \| \leq \delta \) and \( \| A^* - C \| \leq \delta \). Then
\[ \| PA - AP \| = \| P(A^*) - P(A - B) \| = \max\{ \| P(A - C)P^* \|, \| P(A - B)P \| \} \leq \delta . \]

Since \( L'' \) is abelian, Theorem 9.6 implies that \( d(P, L'') \leq \delta \). Choose a self-adjoint element \( R \) in \( L'' \) such that \( \| R - P \| \leq \delta \). Then the spectrum \( \sigma(R) \) is contained in \( [-\delta, \delta] \cup [1-\delta, 1+\delta] \). By the functional calculus, there is a projection \( Q \) in \( L'' \) such that \( \| Q - R \| \leq \delta \), hence \( \| P - Q \| \leq 2 \delta \).

The projection \( Q \) belongs to \( L \). For otherwise, \( \mathcal{A} \) contains an operator \( A = Q^*AQ \) of norm one. Choose \( B \) in \( b_1(B) \) with \( \| A - B \| \leq \delta \). Then
\[ 1 = \| A \| = \| Q^*AQ - P^*BP \| \]
\[ \leq \| (P - Q)AQ \| + \| P^* (A - B)Q \| + \| P^* B (Q - P) \| \]
\[ \leq 2 \delta + \delta + 2 \delta = 5 \delta < 1 . \]

This contradiction establishes our claim. The projection \( Q \) is uniquely determined in \( L'' \) since \( \| Q - Q' \| = 1 \) for distinct projections. Let \( L \) in \( L \) be the subspace such that \( Q = P(L) \). Define \( \theta(M) = L \).

If \( Q = P(L) \) for some \( L \) in \( L \), choose \( B \) in \( B \) so that \( \| (2Q - I) - (2B - I) \| \leq \delta \) and \( \| 2B - I \| \leq 1 \). Then \( \| B \| \leq 1 \) and \( \| Q - B \| \leq \delta /2 \). Next, obtain an idempotent in \( B \) close to \( B \). Compute:
\[ \| B - B^2 \| = \| Q^*B + (Q - B)B \| \]
\[ \leq \| Q^*B - QB \| + \| QB - B \| \| B \| \leq \delta . \]

By Lemma 18.1, there is an idempotent \( F \) in \( B \) with \( \| B - F \| < 5 \delta \). The range \( M = F \mathcal{H} \) must belong to \( \mathcal{M} \), for otherwise there is an operator \( C = (I - F)CF \) in \( B \) of norm one. Choose \( A \) in \( b_1(A) \) with \( \| A - C \| \leq \delta \). Then since \( \| Q - F \| < 6 \delta \), one obtains
1 = \|C\| = \|(1-F)CF-\frac{1}{2}AQ\|
\leq \|(Q-F)CF\| + \|Q\frac{1}{2}C(F-Q)\| + \|Q\frac{1}{2}(C-A)Q\|
< 6\delta + 6\delta + \delta = 13\delta < 1.

This contradiction shows that $M$ indeed belongs to $\mathcal{M}$. And since $P(M)F = F$ and $FP(M) = P(M)$,
\[
\|Q-P(M)\| = \|P(M)\frac{1}{2}(Q-P(M)) + [(Q-P(M))P(M)]^*\|
= \|P(M)\frac{1}{2}(Q-F) + [(Q-F)P(M)]^*\| < 12\delta.
\]
Therefore, $\|Q-P(\theta(M))\| < 14\delta < 1$, so $\theta(M) = L$. Thus $\theta$ is surjective.

Next, we show that $\theta$ is injective. Let $M$ belong to $\mathcal{M}$, and let $L = \theta(M)$. Set $Q = P(L)$ and let $F$ be the idempotent in $B$ found in the previous paragraph. To show that $\theta$ is injective, it suffices to show that $FM = M$. Decompose $M$ as $M \oplus M^\perp$, and write $F$ as a matrix
\[
F = \begin{bmatrix}
F_{11} & F_{12} \\
0 & F_{22}
\end{bmatrix}
\]
with respect to this decomposition. Now
\[
\|F-P(M)\| \leq \|F-Q\| + \|Q-P(M)\| < 6\delta + 2\delta = 8\epsilon < 1.
\]
As $F$ is idempotent, both $F_{11}$ and $F_{22}$ are idempotent and $\|I-F_{11}\| < 1$ and $\|F_{22}\| < 1$. Thus $F_{11} = I$, $F_{22} = 0$ and $FM = M$. So $\theta$ is a bijection.

To see that $\theta$ is a lattice isomorphism, suppose that $M$ and $N$ belong to $\mathcal{M}$. Let $Q_M$ and $Q_N$ be the orthogonal projections onto $\theta(M)$ and $\theta(N)$ respectively, and let $F_M$ and $F_N$ be idempotents in $B$ with
\[
\|Q_M-F_M\| < 6\delta \quad \text{and} \quad \|Q_N-F_N\| < 6\delta.
\]
The operator $F_M F_N$ is an idempotent in $B$ with range $M \wedge N$ since
\[
(F_M F_N)^2 = F_M (F_M F_N) F_M = F_M F_M F_N = F_M F_N.
\]
Similarly, $F_M + F_N - F_M F_N$ is an idempotent in $B$ with range $M \vee N$. A computation yields
\[
\|Q_M Q_N - F_M F_N\| \leq \|Q_M Q_N\| + \|(Q_M - F_M) F_N\|
< 6\delta + 6\delta (1+6\delta) < 14\delta.
\]
Let $R$ be the element of $\mathcal{M}$ such that $Q_M Q_N = P(\theta(R))$. Then $\|P(R) - F_M F_N\| < 16\delta < 1$. So as in the previous paragraph, $R$ equals the range of $F_M F_N$, namely $M \wedge N$. So
\[
\theta(M \wedge N) = \theta(M) \wedge \theta(N).
\]
A similar computation yields $\theta(M \vee N) = \theta(M) \vee \theta(N)$ as well.

Finally, consider arbitrary intersections in $\mathcal{M}$. Let $\{M_\lambda : \lambda \in \Lambda\}$ belong to $\mathcal{M}$ and let $L_\lambda = \theta(M_\lambda)$. Set $M = \land M_\lambda$, $L = \land L_\lambda$. Since $M \leq M_\lambda$, $\theta(M) \leq \theta(M_\lambda) = L_\lambda$ and hence $\theta(M) \leq L$. On the other hand, $\theta^{-1}(L) \leq \theta^{-1}(L_\lambda) = M_\lambda$ so $\theta^{-1}(L) \leq M$ whence $L \leq \theta(M)$. So $\theta(M) = L$. 

In a like manner, one shows that θ also preserves arbitrary sups. So θ is a complete lattice isomorphism.

Now we specialize to nest algebras.

18.3 Lemma. Let ℳ and ℳ be nests on a separable Hilbert space. Suppose that θ is an order isomorphism of ℳ onto ℳ such that \(||θ−id|| = ε < ¼||. Then there is an invertible operator S with \(||S−I|| < 2ε which implements θ.

Proof. Notice that θ preserves dimension. For if \(N_1 < N_2\) in ℳ and \(M_i = θ(N_i)\) for \(i=1,2\), then
\[
d(N_2 ⊕ N_1, M_2 ⊕ M_1) ≤ d(N_2, M_2) + d(N_1, M_1) ≤ 2||θ−id|| < 1 .
\]
So \(dim N_2 ⊕ N_1 = dim M_2 ⊕ M_1\). By the Similarity Theorem 13.20, there is an invertible operator T which implements θ. Furthermore, it can be arranged that there is a unitary operator U such that \(||T−U|| < δ\) where δ is a small positive number satisfying δ < \(ε(1−2ε)/2\).

Apply Arveson’s Distance Formula (Theorem 9.5) to T:
\[
d(T, T(ℳ)) = \sup_{N ∈ ℳ} ||P(N)−TP(N)||
= \sup_{N ∈ ℳ} ||P(N)−P(θ(N))TP(N)||
≤ ||θ−id|| ||T|| < ε(1+δ) < ε+δ .
\]
Thus there is an element V in T(ℳ) with ||T−V|| < ε+δ. Hence ||U−V|| < ε+2δ < 1, so V is invertible.

It will be shown that \(V^{-1}\) belongs to T(ℳ). This is equivalent to showing that VN = N for all N in ℳ. If it were otherwise, there is some N in ℳ such that VN is a proper subspace of N. Pick any unit vector x in N ⊕ VN and choose y in the unit ball of M = θ(N) with ||x−y|| ≤ ε. Since \(T^{-1}M = N\), the vector z = \(T^{-1}y\) belongs to N. And,
\[
1 = ||x−Vz|| ≤ ||x−y|| + ||(T−V)T^{-1}y||
< ε+(ε+δ)(1−δ)^{-1} < (2ε+δ)(1−δ)^{-1} < 1 .
\]
Hence \(V^{-1}\) must belong to T(ℳ).

Therefore S = TV^{-1} implements θ, and
\[
||S−I|| ≤ ||T−V|| ||V^{-1}|| ≤ \frac{ε+δ}{1−ε−δ} < 2ε .
\]

18.4 Theorem. Let ℳ be a nest, and let ℬ be a norm closed algebra such that d(T(ℳ), ℬ) = ε < 1/20. Then ℬ is a nest algebra which is similar to T(ℳ) via an invertible operator S satisfying ||S−I|| < 4ε.
Proof. By Theorem 18.2, $\mathcal{M} = \text{Lat} \mathcal{B}$ is a nest and there is an order isomorphism $\theta$ of $\mathcal{N}$ onto $\mathcal{M}$ with $\| \theta - \text{id} \| \leq 2\epsilon$. By Lemma 18.3, $\theta$ is implemented by an invertible operator $S$ with $\| S-I \| < 4\epsilon$. Now $S \mathcal{T}(\mathcal{N})S^{-1} = \mathcal{T}(\mathcal{M})$. So compute $d(\mathcal{T}(\mathcal{N}), \mathcal{T}(\mathcal{M}))$. If $A$ belongs to $\mathcal{T}(\mathcal{M})$, the distance formula yields
\[
d(A, \mathcal{T}(\mathcal{M})) = \sup_{N \in \mathcal{M}} \| P(\theta N) P(\theta N) \| \leq \sup_{N \in \mathcal{M}} \| P(N) P(N) \| \leq 4\epsilon.
\]
Hence $d(A, b_1(\mathcal{T}(\mathcal{M}))) \leq 8\epsilon$. Likewise, if $B$ belongs to $b_1(\mathcal{T}(\mathcal{M}))$, $d(B, b_1(\mathcal{T}(\mathcal{M}))) \leq 8\epsilon$. Now $B$ is contained in $\mathcal{T}(\mathcal{M})$, and
\[
d(B, \mathcal{T}(\mathcal{M})) \leq d(B, \mathcal{T}(\mathcal{N}))+d(\mathcal{T}(\mathcal{N}), \mathcal{T}(\mathcal{M})) \leq \epsilon+8\epsilon = 9\epsilon < 1.
\]
Hence $B = \mathcal{T}(\mathcal{M})$ and is similar to $\mathcal{T}(\mathcal{N})$ as desired.

The following Corollary is immediate from the proofs.

18.5 Corollary. Let $\mathcal{N}$ and $\mathcal{M}$ be nests on a separable Hilbert space. The following are equivalent
1) $\mathcal{N}$ and $\mathcal{M}$ are close,
2) $\mathcal{T}(\mathcal{N})$ and $\mathcal{T}(\mathcal{M})$ are close,
3) $\mathcal{N}$ and $\mathcal{M}$ are similar via an invertible operator close to $I$.

Now we turn to the von Neumann algebra case. If $\mathcal{A}$ is a von Neumann algebra, let $\mathcal{A}_p$ denote the set of projections in $\mathcal{A}$.

18.6 Lemma. Suppose $\mathcal{A}$ and $\mathcal{B}$ are von Neumann algebras such that $d(\mathcal{A}, \mathcal{B}) = \delta < 1$. Then $d_{\mathcal{H}}(\mathcal{A}_p, \mathcal{B}_p) \leq \delta$.

Proof. Fix $P$ in $\mathcal{A}_p$. Then $2P-I$ belongs to $b_1(\mathcal{A})$, hence there is a $B$ in $b_1(B)$ with $\| (2P-I)-B \| \leq \delta$. Replace $B$ by $(B+B^*)/2$ so that it is self-adjoint and $\| B \| \leq 1$. Then for every vector $x$ in $\mathcal{H}$,
\[
\| Bx \| \geq \| (2P-I)x \| - \delta \| x \| = (1-\delta) \| x \|.
\]
Thus the spectrum $\sigma(B)$ is contained in $[-1,-1+\delta] \cup [1-\delta,1]$. Let $Q$ be the spectral projection $E_{\mathcal{H}}[1-\delta,1]$.

Hence,
\[
\| B-(2Q-I) \| \leq \delta.
\]
\[ \|P-Q\| = \frac{1}{2} \| (2P-I)-B+B-(2Q-I) \| \leq \delta . \]

Repeat the argument with \( B \) and \( A \) interchanged.

18.7 Lemma. Suppose that \( A \) and \( B \) are von Neumann algebras such that \( d(A,B) = \delta < 1/3 \), and let \( Z(A) \) and \( Z(B) \) be their centres. Then \( d_H(Z(A)_p,Z(B)_p) \leq \delta \).

Proof. Let \( P \) be a central projection in \( A \). By Lemma 18.6, there is a projection \( Q \) in \( B \) such that \( \|P-Q\| \leq \delta \). It suffices to show that \( Q \) belongs to \( Z(B) \). Otherwise, there is an operator \( B \) in \( B \) of the form \( B = QBQ^{-1} \neq 0 \). Normalize \( B \) so that \( \|B\| = 1 \), and choose \( A \) in \( b_1(A) \) so that \( \|A-B\| \leq \delta \). Then

\[
1 = \|B\| = \|QBQ^{-1}-PAP^{-1}\| \\
\leq \|(Q-P)BQ^{-1}+||P(B-A)Q^{-1}||+||PA(P-Q)|| \leq 3\delta < 1 .
\]

This is absurd, and the lemma follows.

18.8 Corollary. Suppose that \( A \) and \( B \) are von Neumann algebras such that \( d(A,B) < 1/3 \). If \( A \) is abelian, then \( B \) is also abelian.

Proof. Let \( Q \) be any projection in \( B \). Lemma 18.6 provides a projection \( P \) in \( A \) such that \( \|P-Q\| \leq \delta \). Now \( P \) is central since \( A \) is abelian. Thus by the proof of Lemma 18.7, \( Q \) is also central. As every projection in \( B \) is central, \( B \) is abelian.

18.9 Lemma. Let \( A \) and \( B \) be abelian von Neumann algebras such that \( d_H(A_p,B_p) = \delta < \frac{1}{4} \). Then there exists a unique \( * \)-isomorphism \( \Phi \) of \( A \) onto \( B \) such that \( \sup_{P \in A_p} \| \Phi(P)-P \| \leq \delta \).

Proof. For each projection \( P \) in \( A \), there is a projection \( Q \) in \( B \) such that \( \|P-Q\| \leq \delta \). If \( Q' \) were another projection in \( B \) with \( \|P-Q'\| \leq \delta \), then \( \|Q-Q'\| \leq 2\delta < 1 \). As \( B \) is abelian, this forces \( Q' = Q \). So \( Q \) is unique and thus one can define \( \Phi(P) = Q \). The same argument shows that \( \Phi \) is one to one. Interchanging the role of \( A \) and \( B \) yields a map \( \Psi \) from \( B_p \) to \( A_p \) with the same properties. Moreover, \( \| \Phi(\Psi(Q))-Q \| < 1 \) whence \( \Phi \) is a bijection and \( \Psi = \Phi^{-1} \).

Let \( P_1 \) and \( P_2 \) be orthogonal projections in \( A \). Then

\[ \|P_1+P_2-\Phi(P_1)+\Phi(P_2)\| \leq 2\delta < 1 . \]

Hence \( \|\Phi(P_1)+\Phi(P_2)\| < 2 \) from which it is evident that the two (commuting) projections \( \Phi(P_1) \) and \( \Phi(P_2) \) are orthogonal. Therefore, they sum to a projection, and \( \Phi(P_1+P_2) = \Phi(P_1)+\Phi(P_2) \). In particular, \( \Phi \) is monotone increasing on projections. (If \( P \leq P' \), then \( P = P+(P'-P) \), whence
\( \Phi(P) = \Phi(P) + \Phi(P^\perp - P) \geq \Phi(P) \), the same goes for \( \Phi^{-1} \).

Now let \( P_1 \) and \( P_2 \) be arbitrary projections in \( \mathcal{A} \). Then \( P_1 P_2 \leq P_i \) for \( i = 1 \) and \( 2 \), hence \( \Phi(P_1 P_2) \leq \Phi(P_i) \) for \( i = 1 \) and \( 2 \) and so \( \Phi(P_1 P_2) \leq \Phi(P_1) \Phi(P_2) \). This holds for \( \Phi^{-1} \) as well, so

\[
P_1 P_2 \leq \Phi^{-1}(\Phi(P_1) \Phi(P_2)) \leq \Phi^{-1}(\Phi(P_1)) \Phi^{-1}(\Phi(P_2)) = P_1 P_2.
\]

Consequently, \( \Phi(P_1 P_2) = \Phi(P_1) \Phi(P_2) \). Also, consider

\[
P_1 \vee P_2 = P_1 + P_2 - P_1 P_2
\]

which is the projection onto the span of \( P_1 \mathcal{H} \) and \( P_2 \mathcal{H} \). One has

\[
\Phi(P_1 \vee P_2) = \Phi(I - P_1 P_2^\perp) = I - \Phi(P_1)^\perp \Phi(P_2)^\perp = \Phi(P_1) \vee \Phi(P_2).
\]

So \( \Phi \) is a lattice isomorphism of \( \mathcal{A}_p \) onto \( \mathcal{B}_p \).

Extend \( \Phi \) to all finite linear combinations of \( \mathcal{F} \) of \( \mathcal{A}_p \) by linearity. Let \( P_1, \ldots, P_n \) be pairwise orthogonal projections in \( \mathcal{A} \) with sum \( I \). Consider a self-adjoint element \( A = \sum_{i=1}^{n} \lambda_i P_i \) with \( |\lambda_i| \leq 1 \) for \( 1 \leq i \leq n \). Then \( A \) is in the convex hull of

\[
\left\{ \sum_{i=1}^{n} \epsilon_i P_i : \epsilon_i = \pm 1 \right\} = \left\{ 2P - I : P = \sum_{i \in S} P_i, S \subseteq \{1, \ldots, n\} \right\}.
\]

Thus

\[
\| \Phi(A) - A \| \leq \sup_{P \in \mathcal{A}_p} \| \Phi(2P - I) - (2P - I) \|
\]

\[
= 2 \sup_{P \in \mathcal{A}_p} \| \Phi(P) - P \|. \tag{18.9.1}
\]

Applying this to the real and imaginary parts of an element \( X \) in \( \mathcal{F} \) yields

\[
\| \Phi(X) - X \| \leq 4\delta \| X \|.
\]

Thus \( \Phi \) is norm continuous. Since \( \mathcal{F} \) is norm dense in \( \mathcal{A} \), one can extend \( \Phi \) to a map of \( \mathcal{A} \) into \( \mathcal{B} \). The range of \( \Phi \) contains the dense subspace of all finite linear combinations of \( \mathcal{B}_p \). Also \( \Phi \) is bounded below by \( 1 - 2\delta \) on the self-adjoint part of \( \mathcal{A} \). Hence \( \Phi \) is surjective. It is easy to see that \( \Phi \) is multiplicative in \( \mathcal{F} \), and so the extension is multiplicative. So \( \Phi \) is a *-isomorphism of \( \mathcal{A} \) onto \( \mathcal{B} \).

18.10 Lemma. Let \( \Phi \) be a linear map of a real subspace \( D \) in \( \mathcal{B}(\mathcal{H}) \) into \( \mathcal{B}(\mathcal{H}) \) such that \( \| \Phi(A) - A \| \leq \delta \| A \| \). Then for any pairwise orthogonal family of projections \( \{ P_\lambda : \lambda \in \Lambda \} \) in \( D \),

\[
\sum_{\lambda} (\Phi(P_\lambda) - P_\lambda)^2 \leq \delta^2 I.
\]
Proof. It suffices to prove this for any finite family, say $P_1,\ldots,P_n$. For each $\epsilon$ in $\{-1,1\}^n$, let $P_\epsilon = \sum_{j=1}^n \epsilon_j P_j$. Then $\|P_\epsilon\| = 1$, so

$$\delta^2 I \geq (\Phi(P_\epsilon)-P_j)^2 = \sum_{i=1}^n \sum_{j=1}^n \epsilon_i \epsilon_j (\Phi(P_i)-P_i)(\Phi(P_j)-P_j) .$$

If one sums $\epsilon_i \epsilon_j$ over all possible choices of $\epsilon$ for fixed $i$, $j$, one obtains $2^n \delta^4$. Thus averaging over all $2^n$ values of $\epsilon$ yields

$$\delta^2 I \geq \sum_{j=1}^n (\Phi(P_j)-P_j)^2 . \tag*{\blacksquare}$$

18.11 Lemma. Let $X = UR$ be the polar decomposition of an operator $X$. Suppose that $\|I-X\| = \delta < 1$. Then $\|I-U\| \leq \sqrt{2\delta(1+(1-\delta^2)^{1/4})^{-6}}$.

Proof. First, $X$ is invertible so $U$ is unitary. Moreover,

$$\|Im\ U\| = \|Im(U-R)\| \leq \|U-R\|$$

$$= \|U^*-R\| = \|U(U^*-R)\| = \|I-X\| = \delta .$$

So the spectrum $\sigma(U)$ belongs to

$$\{\lambda \in \mathbb{C}: |\lambda| = 1, |Im\ \lambda| \leq \delta, dist(\lambda, [0,1]) \leq \delta\} .$$

For such $\lambda$,

$$|\lambda-1|^2 \leq |\sqrt{1-\delta^2}+i\delta-1|^2 = \frac{2\delta^2}{1+\sqrt{1-\delta^2}} .$$

The norm estimate is now immediate since $\|U-I\| = spr(U-I)$.

18.12 Theorem. Let $\mathcal{A}$ be an abelian von Neumann algebra, and let $\mathcal{B}$ be a von Neumann algebra such that $d(\mathcal{A},\mathcal{B}) = \delta < 1/3$. Then there is a unitary operator $U\in(\mathcal{A}\cup\mathcal{B})''$ such that $B = U^*\mathcal{A}U$, and

$$\|U-I\| \leq 2\delta(1+(1-\delta^2)^{1/4})^{-6} \leq \frac{15}{7} \delta .$$

Proof. By Corollary 18.8, $B$ is abelian. By Lemmas 18.6 and 18.9, there is a $*$-isomorphism $\Phi$ of $\mathcal{A}$ onto $B$ such that $\sup_{P\in\mathcal{A}_p} \|\Phi(P)-P\| \leq \delta$. So by (18.9.1), $\|\Phi(A)-A\| \leq 2\delta \|A\|$ for every self-adjoint element of $\mathcal{A}$. By Lemma 18.10, if $P_1,\ldots,P_n$ are pairwise orthogonal projections in $\mathcal{A}$,

$$\sum_{j=1}^n (\Phi(P_j)-P_j)^2 \leq 4\delta^2 I .$$

Consider the collection $\mathcal{E}$ of finite partitions of the identity into pairwise orthogonal projections in $\mathcal{A}$. Put an order on $\mathcal{E}$ given by $(P_1,\ldots,P_n) \ll (Q_1,\ldots,Q_m)$ if each $P_j$ is the sum of certain $Q_i$'s. For each $\alpha$ in $\mathcal{E}$, let
\[ X_\alpha = \sum_{j=1}^{n} \Phi(P_j)P_j \]

Note that \( X_\alpha P_j = \Phi(P_j)X_\alpha \) for \( 1 \leq j \leq n \). Hence if \( (P,P^\perp) \ll \alpha \), \( X_\alpha P = \Phi(P)X_\alpha \).

Each \( X_\alpha \) is a norm one element in \((\mathcal{A} \cup \mathcal{B})^n\). Let \( X \) be a weak* limit of a confinal subnet \( \{ X_\beta : \beta \in \mathcal{E}^\prime \} \) of \( \{ X_\alpha \} \). Then for each projection \( P \in \mathcal{A} \), there is a \( \beta \gg (P,P^\perp) \) in \( \mathcal{E}^\prime \). Hence \( XP = \Phi(P)X \) for all \( P \) in \( \mathcal{A} \).

By linearity,

\[ XA = \Phi(A)X \]

for all \( A \) in \( \mathcal{A} \). Now, for each \( \beta \)

\[
0 \leq I - X_\beta X_\beta = \sum_{j=1}^{n} P_j - \sum_{j=1}^{n} P_j \Phi(P_j)P_j
= \sum_{j=1}^{n} P_j (P_j - \Phi(P_j))P_j \leq \delta I
\]

Hence \( X \) is invertible. Moreover, for each \( \beta \)

\[
(I - X_\beta)(I - X_\beta) = (I - X_\beta) + (I - X_\beta^*) - (I - X_\beta X_\beta) \leq I - X_\beta + I - X_\beta^*
= \sum_{j=1}^{n} P_j (P_j - \Phi(P_j)P_j + \Phi(P_j) - P_j \Phi(P_j))
= \sum_{j=1}^{n} (\Phi(P_j) - P_j)^2 \leq 4\delta^2 I
\]

Hence \( \|I - X_\beta\| \leq 2\delta \), whence \( \|I - X\| \leq 2\delta \).

Let \( X = U(X^*X)^{1/2} \) be the polar decomposition of \( X \). Since \( X \) is invertible, \( U \) is unitary and it belongs to \((\mathcal{A} \cup \mathcal{B})^n\). For \( A \) in \( \mathcal{A} \),

\[ X^*XA = X^*\Phi(A)X = (\Phi(A^*)X^*)^*X = AX^*X \]

Thus \((X^*X)^{1/2}\) commutes with \( \mathcal{A} \). So

\[
(UA - \Phi(A)U)(X^*X)^{1/2} = U(X^*X)^{1/2}A - \Phi(A)U(X^*X)^{1/2}
= XA - \Phi(A)X = 0
\]

But \((X^*X)^{1/2}\) is invertible. So \( A = U^*\Phi(A)U \) for all \( A \) in \( \mathcal{A} \). So \( U^*B^*U = \mathcal{A} \).

By Lemma 18.11,

\[
\|U-I\| \leq 2\sqrt{2} \delta (1+(1-4\delta^2)^{1/2})^{-1/2}
< \delta (2\sqrt{2})(1+(1-4/9)^{1/2})^{-1/2} < \frac{15}{7} \delta
\]
18.13 Corollary. Let $\mathcal{A}$ be a von Neumann algebra with abelian commutant, and let $\mathcal{B}$ be a von Neumann algebra such that $d(\mathcal{A}, \mathcal{B}) = \delta < 1/6$. Then there is a unitary operator $U$ in $(\mathcal{A} \cup \mathcal{B})''$ such that $\mathcal{B} = U^* \mathcal{A} U$ and

$$
\|U-I\| \leq 2 \sqrt{2} \delta (1 + 1 - 4\delta^2)^{1/2} < (2.03) \delta.
$$

Proof. By Lemma 18.7 and Theorem 18.12, there is a unitary operator $U$ satisfying the norm condition in $(Z(\mathcal{A}) \cup Z(\mathcal{B}))'' \subseteq (\mathcal{A} \cup \mathcal{B})''$ such that

$$
Z(UBU^*) = UZ(\mathcal{B})U^* = Z(\mathcal{A}) = \mathcal{A}'.
$$

Thus $UBU^*$ is contained in $Z(UBU^*) = \mathcal{A}$. Compute $d(B, UBU^*)$. Every $B$ in $\mathcal{B}$ satisfies

$$
d(B, UB_1(B)U^*) \leq \|B - UBU^*\| = \|BU - UB\| \leq 2\|U-I\| < 5\delta.
$$

The same holds for $B'$ in $UB_1(B)U^*$, so $d(B, UBU^*) < 5\delta$. Hence

$$
d(\mathcal{A}, UBU^*) < \delta + 5\delta < 1.
$$

If $UBU^*$ were a proper subspace of $\mathcal{A}$, it would be at a distance of one. Thus $UBU^* = \mathcal{A}$. \hfill \qed

Notes and Remarks.

Perturbations of von Neumann algebras were first considered by Kadison and Kastler [1]. They proved that close von Neumann algebras can be decomposed into central summands corresponding to type $I_n$, $II_1$, $II_{\infty}$, and $III$ each of which is close to the corresponding summand of the other algebras. The material in this chapter on type I von Neumann algebras is due to Christensen [1]. His general result is for all type I algebras, and the ideas are sketched in the exercises. J. Phillips [1] got these results also except for the estimate on $\|U-I\|$. There is the related interesting question for separable $C^*$-algebras. Non-separable $C^*$-algebras which are close need not be unitarily equivalent (Choi-Christensen [1]). The interested reader shall also consult Phillips [2], Johnson [4], and Christensen [6].

Perturbations of nest algebras were considered by Lance [2] who proved Lemma 18.3 and Corollary 18.5 using cohomological methods. The approach taken here using the Similarity Theorem and Theorem 18.2 is due to Davidson [7] and Choi-Davidson [1].

Exercises

18.1 (Choi-Davidson) Let $L$ be a finite commutative subspace lattice. Show that there is an $\epsilon > 0$ and $C < \infty$ so that if $\mathcal{A}$ is a norm closed algebra such that $\text{dist}(\text{Alg} L, \mathcal{A}) < \epsilon$, then $\mathcal{A}$ is similar to $\text{Alg} L$ via an invertible operator $S$ with $\|S-I\| \leq C\epsilon$. 
18.2 (Choi-Davidson)
(a) For \( t \in \mathbb{C} \), let
\[
\mathcal{A}_t = \left\{ \begin{bmatrix} \lambda & a \\ 0 & \lambda + at \end{bmatrix} : \lambda, a \in \mathbb{C} \right\}.
\]
Show that \( \text{dist}(\mathcal{A}_0, \mathcal{A}_t) \leq |t| \), but \( \mathcal{A}_0 \) is not algebraically isomorphic to \( \mathcal{A}_t \) for any \( t \neq 0 \).
(b) For \( t \in \mathbb{C} \), let \( S_t \subseteq M_2 \) and \( \mathcal{A}_t \subseteq M_4 \) be given by
\[
S_t = \left\{ \begin{bmatrix} a & b \\ c & at \end{bmatrix} : a, b, c \in \mathbb{C} \right\}, \quad \mathcal{A}_t = \left\{ \begin{bmatrix} \lambda I & S \\ 0 & \lambda I \end{bmatrix} : \lambda \in \mathbb{C}, S \in S_t \right\}.
\]
Define \( \phi_t : \mathcal{A}_0 \to \mathcal{A}_t \) by
\[
\phi_t \begin{bmatrix} \lambda & 0 & a & b \\ 0 & \lambda & c & 0 \\ 0 & 0 & \lambda & 0 \\ 0 & 0 & 0 & \lambda \end{bmatrix} = \begin{bmatrix} \lambda & 0 & a & b \\ 0 & \lambda & c & at \\ 0 & 0 & \lambda & 0 \\ 0 & 0 & 0 & \lambda \end{bmatrix}.
\]
Show that \( \phi_t \) is an isomorphism and \( \|\phi_t - \phi_0\| = |t| \). Show that \( \mathcal{A}_t \) is not similar to \( \mathcal{A}_0 \) if \( t \neq 0 \).

18.3 (Christensen) Let \( \mathcal{A} \) be a type I von Neumann algebra, and let \( B \) be a von Neumann algebra such that \( d(\mathcal{A}, B) = \delta < \frac{1}{200} \). Let \( P \) be a maximal abelian projection in \( \mathcal{A} \), and let \( Q \) be a projection in \( B \) such that \( \|P - Q\| \leq \delta \).
(a) Show that \( \{Z(\mathcal{A}) \cup P\}'' \) and \( \{Z(B) \cup Q\}'' \) are close, and apply Theorem 18.7 to replace \( B \) by \( \widetilde{B} \) with \( Z(\mathcal{A}) = Z(\widetilde{B}) \) and \( P = Q \).
(b) Prove that \( \widetilde{Q} \) is an abelian projection in \( \widetilde{B} \) and hence deduce that \( B \) is type I. Show that \( PAP \) and \( \widetilde{P} \widetilde{B} \widetilde{P} \) are close, and apply Theorem 18.7 again to replace \( \widetilde{B} \) by \( C \) in which \( Z(\mathcal{A}) = Z(C) \), \( P \in C \), and \( PAP = PCP \), and \( d(\mathcal{A}, C) \) is small.
(c) Let \( \Phi_A \) and \( \Phi_C \) be the restriction maps of \( \mathcal{A}' \) and \( C' \) to \( PH \) respectively, and note that \( \Phi = \Phi_C^{-1} \Phi_A \) is a *-isomorphism. Show that \( d(\mathcal{A}', C') \leq 4d(\mathcal{A}, C) \) and hence deduce \( \|\Phi - \text{id}\| < 8\delta \).
(d) Let \( 1 \leq m \leq \infty \) and let \( P_m \) be the central summand of \( \mathcal{A} \) corresponding to the type \( I_m \) part of \( \mathcal{A}' \). Let \( E_{ij} \) be a set of matrix units for \( P_m \mathcal{A}' \). Set \( X_m = \sum_{j=1}^{m} \Phi(E_{j1})E_{1j} \). Show that
$X_m A = \Phi(A) X_m$ for all $A$ in $P_m \mathcal{A}'$. Show that $X_m$ is invertible, and hence deduce that $\mathcal{A}'$ and $\mathcal{C}'$ are unitarily equivalent.

(e) Estimate $\|I - X_m\|$ and hence find a unitary $U$ such that $UBU^* = \mathcal{A}$ and $\|U - I\| \leq C\delta$ for a universal constant $C$. (Caveat: this is very hard.)
19. Derivations of Nest Algebras

In this chapter, derivations of nest algebras will be computed. Derivations are defined in Chapter 10. A brief consideration of higher cohomology is contained in the notes. Also, there is an appendix on the $K_0$ group of a nest algebra. The first result is automatic continuity, and it parallels Theorem 10.3.

19.1 Theorem. Let $\mathcal{A}$ be a weak* closed subalgebra of $B(\mathcal{H})$. Let $M$ be a dual normal $\mathcal{A}$ module, and let $\delta: \mathcal{A} \to M$ be a derivation. Then there is a central projection $P$ in $\mathcal{A} \cap \mathcal{A}^*$ such that $D_P(A) = \delta(AP)$ is continuous and $(\mathcal{A} \cap \mathcal{A}^*)(I-P)$ is finite dimensional.

Proof. As in Theorem 10.3, let $J$ be the set of elements $J$ in $\mathcal{A} \cap \mathcal{A}^*$ such that $D_J(A) = \delta(AJ)$ is a continuous map. Let $R_X$ denote multiplication on the right by $X$. If $B$ belongs to $\mathcal{A} \cap \mathcal{A}^*$, then

$$D_{BJ}(A) = \delta(ABJ) = D_J R_B(A)$$

and

$$D_{JB}(A) = \delta(AJB) + AJ\delta(B) = (R_B D_J + R_{JSB})(A).$$

Consequently, $J$ is a two sided ideal in $\mathcal{A} \cap \mathcal{A}^*$.

By Theorem 10.3, the restriction of $\delta$ to $\mathcal{A} \cap \mathcal{A}^*$ is bounded, say by $K$. Suppose that $J_\alpha$ is a net of elements in the unit ball of $J$ converging weak* to $J$. Then

$$D_J(A) = \delta(A)J + A\delta(J) = \lim w^* \delta(A)J_\alpha + A\delta(J) = \lim w^* D_{J_\alpha}(A) + A\delta(J - J_\alpha).$$

So $D_J$ is the pointwise limit of the continuous maps $T_\alpha = D_{J_\alpha} + R_{S(J - J_\alpha)}$. Moreover, from the second line,

$$\|T_\alpha(A)\| \leq \|\delta(A)\| + \|A\| K$$

for all $\alpha$. By the Uniform Boundedness Principle, $\sup \|T_\alpha\| < \infty$. Hence $D_J$ is continuous. By the Krein-Smulyan Theorem, it follows that $J$ is weak* closed.

It now follows that $J$ contains a maximum idempotent $P$ which is central in $\mathcal{A} \cap \mathcal{A}^*$ such that $J = (\mathcal{A} \cap \mathcal{A}^*)P$. Suppose that $(\mathcal{A} \cap \mathcal{A}^*)P^\perp$ is not finite dimensional. Then there are pairwise orthogonal projections $E_n$ in $(\mathcal{A} \cap \mathcal{A}^*)P^\perp$. By the definition of $J$, $D_{E_n}$ is unbounded. Choose $A_n$ in $\mathcal{A}$
with \( \|A_n\| < 2^{-n} \) and \( \|\delta(A_n E_n)\| > 2^n \). Let \( A = \sum_{n=1}^{\infty} A_n \). Then
\[
2^n < \|\delta(A_n E_n)\| = \|\delta(AE_n)\| = \|\delta(A)E_n + A\delta(E_n)\| \leq \|\delta(A)\| + K\|A\| .
\]
This contradiction shows that \((\mathcal{A} \cap \mathcal{A}^*)^\perp\) is finite dimensional. \(\blacksquare\)

19.2 Corollary. Let \( \delta \) be a derivation on a CSL algebra \( \mathcal{A} \). Then \( \delta \) is continuous.

Proof. By Theorem 19.1, there is a central projection \( P \) in \( \mathcal{A} \cap \mathcal{A}^* = L^1 \) (where \( L = \text{Lat} \mathcal{A} \)) such that \((\mathcal{A} \cap \mathcal{A}^*)^\perp\) is finite dimensional and \( P \) is continuous. The projection \( P^\perp \) is the sum \( \sum_{i=1}^{k} Q_i \) of minimal projections in \( L^\perp \), each of which is finite rank since \((\mathcal{A} \cap \mathcal{A}^*)^\perp = \sum_{i=1}^{k} \oplus B(Q_i, \mathcal{M}) \) is finite dimensional. Applying Theorem 19.1 to \( \delta^*(X) = \delta(X^*)^* \) on \( \mathcal{A}^* \), one obtains a central projection \( Q \) in \( \mathcal{A} \cap \mathcal{A}^* \) such that \( Q^\perp(\mathcal{A} \cap \mathcal{A}^*) \) is finite dimensional and \( QD(A) = \delta(QA) \) is continuous. As above, \( Q^\perp = \sum_{j=1}^{l} Q_j \) is the sum of minimal finite rank projections in \( L^\perp \). Hence
\[
\delta(A) = \delta(AP) + \delta(QAP^\perp) + \delta(Q^\perp AP^\perp) .
\]
So \( \delta = D_P + QD R P^\perp + L_{Q^\perp} R P^\perp \) is the sum of two continuous maps and a linear map acting on the finite dimensional space \( Q^\perp AP^\perp \). Thus \( \delta \) is continuous. \(\blacksquare\)

19.3 Lemma. Let \( \delta \) be a bounded derivation on a Banach algebra \( \mathcal{A} \). Then \( \alpha_t = e^{it\delta} \), \( t \in \mathbb{R} \), is a continuous one parameter group of automorphisms of \( \mathcal{A} \), and \( \delta = \lim_{t \to 0}^{-1}(\alpha_t - \text{id}) \).

Proof. If \( \delta \) is a derivation, then \( \alpha = e^{\delta} = \sum_{n=0}^{\infty} \delta^n / n! \) is a bounded linear map. One readily verifies by induction the formula
\[
\delta^n(xy) = \sum_{k=0}^{n} \binom{n}{k} \delta^k(x) \delta^{n-k}(y) .
\]
So
\[
\alpha(xy) = \sum_{n=0}^{\infty} \frac{\delta^n(xy)}{n!} = \sum_{n=0}^{\infty} \sum_{k=0}^{n} \frac{\delta^k(x)}{k!} \frac{\delta^{n-k}(y)}{n-k!} .
\]
\[= \sum_{k=0}^{\infty} \frac{\delta^k(x)}{k!} \left( \sum_{j=0}^{\infty} \frac{\delta^j(y)}{j!} \right) = \alpha(x) \alpha(y).\]

Now \(t\delta\) is a derivation for every \(\delta\), thus \(\alpha_t\) is a homomorphism for every \(t\). Moreover, \(\alpha_s \alpha_t = e^{s \delta} e^{t \delta} = e^{(s+t)\delta} = \alpha_{s+t}\) so this forms a one parameter group of automorphisms. Finally,

\[t^{-1}(\alpha_t - id) = \delta + t \sum_{n=2}^{\infty} t^{n-2} \frac{\delta^n}{n!}.\]

For \(|t| \leq 1\), \[\sum_{n=2}^{\infty} t^{n-2} \frac{\delta^n}{n!} < c\|\delta\|^2\], so \[\lim_{t \to 0} t^{-1}(\alpha_t - id) = \delta.\]

**19.4 Lemma.** Let \(\mathcal{N}\) be a nest. For every operator \(A\) in \(B(\mathcal{N})\),

\[\text{dist}(A \mathcal{I}) \leq 2\|\delta_A | T(\mathcal{N})\|\].

**Proof.** By Theorem 8.3 and Corollary 8.5, there is an expectation \(\Phi\) of \(B(\mathcal{N})\) onto \(\mathcal{N}^n\) so that \(B = \Phi(A)\) belongs to the weak* closed convex hull of \(\{UAU^*: U \in \mathcal{U}(\mathcal{N})\}\). Hence

\[\|B - A\| \leq \sup \{\|UAU^* - A\|: U \in \mathcal{U}(\mathcal{N})\}\]

\[= \sup \{\|\delta_A(U^n)\|: U \in \mathcal{U}(\mathcal{N})\} \leq \|\delta_A | T(\mathcal{N})\|\].

Also, for \(T\) in \(T(\mathcal{N})\),

\[\|\delta_B(T)\| \leq \sup \{\|UAU^*T\|: U \in \mathcal{U}(\mathcal{N})\}\]

\[= \sup \{\|A(U^TU)U^n\|: U \in \mathcal{U}(\mathcal{N})\} \leq \|\delta_B | T(\mathcal{N})\| \|T\|\].

Fix \(N\) in \(\mathcal{N}\), and let \(x \in N\) and \(y \in N^\perp\) be unit vectors. Then

\[|(\delta_B(x \otimes y^*)y, x)| = |(Bx, x) - (By, y)| \leq \|\delta_B | T(\mathcal{N})\|\].

Let \(\lambda\) and \(\mu\) be points in \(\sigma(B)\) so that \(|\lambda - \mu|\) is maximal. Since \(B\) commutes with \(\mathcal{N}\), it is possible to find an \(N\) in \(\mathcal{N}\) so that one, say \(\lambda\), belongs to \(\sigma(B|N)\) and the other, \(\mu\), belongs to \(\sigma(B|N^\perp)\). As \(B\) is normal, it is easy to approximate \(\lambda\) by \((Bx, x)\) where \(x\) is a unit vector in \(N\) and approximate \(\mu\) by \((By, y)\) where \(y\) is a unit vector in \(N^\perp\). Thus

\[\|\delta_B | T(\mathcal{N})\| \geq \text{diam}(\sigma(B)) \geq \text{dist}(B \mathcal{I})\].

Hence

\[\text{dist}(A \mathcal{I}) \leq \|A - B\| + \text{dist}(B \mathcal{I}) \leq 2\|\delta_A | T(\mathcal{N})\|\].

**19.5 Corollary.** The commutant of \(T(\mathcal{N})\) is trivial.

**Proof.** If \(\delta_A | T(\mathcal{N}) = 0\), then \(A\) is scalar by Lemma 19.4.
19.6 Corollary. Let $\alpha$ be an automorphism of a nest algebra $\mathcal{T}(\mathcal{N})$. Then there is an invertible operator $A$ with $\|A-I\| \leq 4\|\alpha-id\|$ such that $\alpha = AdA$.

Proof. By Theorem 17.12, $\alpha$ is spatial, say $\alpha = AdA$. By Corollary 19.5, $A$ is unique up to a scalar factor. Normalize $A$ so that $\|A\| = 1$. For $T$ in $\mathcal{T}(\mathcal{N})$,

$$\|\delta_A(T)\| = \|AT-\overline{T}A\| = \|(\alpha(T)-T)A\| \leq \|\alpha-id\| \|A\| \|T\|.$$ 

By Lemma 19.4, there is a scalar $\lambda$ so that $\|A-\lambda I\| \leq 2\|\alpha-id\|$. As $\|A\| = 1$, it follows that $|1-|\lambda|| \leq \|A-\lambda I\|$, so $\|A-\lambda I\| \leq 4\|\alpha-id\|$. Replace $A$ by $\lambda^{-1}A$.

19.7 Theorem. Every derivation $\delta$ of a nest algebra $\mathcal{T}(\mathcal{N})$ is inner.

Proof. By Corollary 19.2, $\delta$ is bounded. Let $\alpha_t = e^{it\delta}$, $t \in \mathbb{R}$, be the continuous group of automorphism generated by $\delta$. There is an $\epsilon > 0$ so that $|t| < \epsilon$ implies $\|\alpha_t-id\| < 1$. By Corollary 17.15, $\alpha_t$ is inner. Let $A_t$ be an invertible element in $\mathcal{T}(\mathcal{N})$ so that $\alpha_t = Ad(A_t)$. By Corollary 19.6, $A_t$ can be normalized so that $\|A_t-I\| \leq 4\|\alpha_t-id\|$. By Lemma 19.3, $t^{-1}\|\alpha_t-id\|$ is bounded. So $D_n = n(A_{1/n}-I)$ is a bounded net, so there is a weak* convergent subnet $D_{n_\gamma}$ with limit $D$ in $\mathcal{T}(\mathcal{N})$. Again by Lemma 19.3, one obtains

$$\delta_D(T) = \lim D_{n_\gamma}T-\overline{T}D_{n_\gamma} = \lim n_\gamma(A_{1/n_\gamma}T-\overline{T}A_{1/n_\gamma})$$

$$= \lim n_\gamma(\alpha_{1/n_\gamma}-id)(T)A_{1/n_\gamma} = \delta(T).$$

So $\delta = \delta_D$ is inner.

There is the analogous theorem for $\mathcal{Q}\mathcal{T}(\mathcal{N})$, based on Theorem 17.20.

19.8 Lemma. Let $\mathcal{A}$ be an algebra of operators containing the compact operators $K$. Then every derivation $\delta$ on $\mathcal{A}$ is spatial.

Proof. Every compact operator $K$ factors as $K = K_1K_2$ where both $K_1$ and $K_2$ are compact. So $\delta(K) = K_1\delta(K_2)+\delta(K_1)K_2$ is compact. By Theorem 10.6, $\delta[K$ is weak* continuous so extends to a derivation $\delta'$ of $\mathcal{B}(\mathcal{N})$. By Theorem 10.8, $\delta' = \delta_X$ for some $X$ in $\mathcal{B}(\mathcal{N})$. For any operators $A$ in $\mathcal{A}$ and $K$ in $K$,
\[ \delta(A)K = \delta(\mathcal{A}K) - A\delta(K) \]
\[ = \delta_X(\mathcal{A}K) - A\delta_X(K) = \delta_X(A)K. \]
This holds for all \( K \), whence \( \delta = \delta_X. \)

\textbf{19.9 Lemma.} \( e^{tX} = Ad e^{X}. \)

\textbf{Proof.} Let \( A \) be an operator. Then
\[
Ad e^{X}(A) = \left( \sum_{k=0}^{\infty} \frac{X^k}{k!} \right) A \left( \sum_{j=0}^{\infty} \frac{(-X)^j}{j!} \right)
= \sum_{n=0}^{\infty} \sum_{j=0}^{n} \frac{X^{n-j}}{n!} A \frac{(-X)^j}{j!}
= \sum_{n=0}^{\infty} \frac{1}{n!} \sum_{j=0}^{n} \binom{n}{j} (-1)^j X^{n-j} AX^j
\]
and
\[
e^{tX}(A) = \sum_{n=0}^{\infty} \frac{1}{n!} \delta_X^n(A).
\]
Now \( \delta_X^0(A) = A \) and \( \delta_X(A) = XA - AX \). One readily establishes by induction that \( \delta_X^n(A) = \frac{1}{n!} \sum_{j=0}^{n} \binom{n}{j} (-1)^j X^{n-j} AX^j \). So equality is evident.

\textbf{19.10 Theorem.} Every derivation \( \delta \) of a quasitriangular algebra \( \mathcal{Q} \mathcal{T}(\mathcal{N}) \) is inner.

\textbf{Proof.} By Lemma 19.8, \( \delta = \delta_X \) for some \( X \) in \( \mathcal{B}(\mathcal{H}) \). By Lemma 19.3, one defines the continuous automorphism group \( \alpha_t = e^{it} = Ad e^{iX} \) by Lemma 19.9. For \( |t| \) sufficiently small, \( \|\alpha_t - id\| < 1 \). So by Theorem 17.20, \( \alpha_t \) is inner so \( \alpha_t = Ad S_t \) and \( S_t \) belongs to \( \mathcal{Q} \mathcal{T}^{-1}(\mathcal{N}) \). But \( S_t \) is determined up to a scalar factor since \( K' = C I \). Thus \( e^{itX} \) belongs to \( \mathcal{Q} \mathcal{T}(\mathcal{N}) \). So
\[
X = \lim_{t \to 0} \frac{e^{itX} - I}{t}
\]
begins to \( \mathcal{Q} \mathcal{T}(\mathcal{N}) \). That is, \( \delta = \delta_X \) is inner.

Next, we consider derivations into the compact operators. But first we require a more general result.
19.11 Proposition. Let $\mathcal{N}$ be a nest, and let $B$ be a weak* closed algebra containing $\mathcal{T}(\mathcal{N})$. Then every derivation $\delta$ of $\mathcal{T}(\mathcal{N})$ into $B$ is inner.

**Proof.** Let $\delta'$ be the restriction of $\delta$ to $\mathcal{H}'$, and note that $B$ is a dual normal $\mathcal{H}'$ module. By Theorem 10.8, $\delta' = \delta_E$ for some $E$ in $B$. Let $\delta_1 = \delta - \delta_E$. Then $\delta_1(P) = 0$ for every $P$ in $\mathcal{H}'$. For every $T$ in $\mathcal{T}(\mathcal{N})$ and $N$ in $\mathcal{N}$,

$$P(N)^{-1}\delta_1(T)P(N) = \delta_1(P(N)^{-1}TP(N)) = 0.$$ 

So $\delta_1$ is a derivation of $\mathcal{T}(\mathcal{N})$ into itself. By Theorem 19.7, $\delta_1 = \delta_A$ for some $A$ in $\mathcal{T}(\mathcal{N})$. Thus $\delta = \delta_{A+E}$ is inner. ■

19.12 Theorem. Every derivation $\delta$ of a nest algebra $\mathcal{T}(\mathcal{N})$ into the compact operator $\mathcal{K}$ is inner.

**Proof.** First, one has that $\delta$ maps $\mathcal{T}(\mathcal{N})$ into $B(\mathcal{H})$. So by Proposition 19.11, $\delta = \delta_X$ for some $X$ in $B(\mathcal{H})$. The restriction of $\delta$ to $\mathcal{H}'$ is compact valued. Thus by the Johnson-Parrott Theorem 10.12, $X$ belongs to $\mathcal{H}'+\mathcal{K}$. So there is a compact operator $K$ and an operator $T$ in $\mathcal{H}'$ so that $\delta_T = \delta - \delta_K$ is zero on $\mathcal{H}'$, and is compact valued on $\mathcal{T}(\mathcal{N})$. Now consider four cases, depending on the structure of $\mathcal{N}$:

**Case 1.** $\mathcal{N}$ contains an element $N$ such that $N$ and $N^\perp$ are infinite dimensional. Let $U$ be any isometry of $N^\perp$ onto $N$. Let $A$ belong to $P(N)B(\mathcal{H})P(N)$. Then $AU$ belongs to $\mathcal{T}(\mathcal{N})$. Let $T_1 = TP(N)$ and $T_2 = TP(N)^{-1}$. Then

$$\delta_{T_1}(A) = \delta_{T_1}(A)P(N) = \delta_{T_1}(A)UU^* = (\delta_{T_1}(AU) - A\delta_{T_1}(U))U^*$$

is compact. Thus $\delta_{T_1}$ is a derivation of $B(N)$ into $K$. So $T_1 = \lambda_1 P(N)+K_1$ where $K_1$ is a compact operator on $N$. Similarly, $T_2 = \lambda_2 P(N)^{-1}+K_2$. Finally,

$$\delta_{T_2}(U) = (\lambda_1-\lambda_2)U+K_1U-UK_2.$$ 

So $\lambda_1 = \lambda_2$, and $T$ is scalar plus compact. Thus $\delta_T = \delta_{K_1+K_2}$ whence $\delta = \delta_{K+K_1+K_2}$ is inner.

**Case 2.** $\mathcal{N}$ contains an element $N_\infty$ of finite codimension, and $\{N \in \mathcal{N}: N < N_\infty\} = \{0 = N_0 < N_1 < \ldots < N_k < \ldots\}$ is a sequence of finite dimensional subspaces with $\bigvee_{k \geq 1} N_k = N_\infty$. Let $A_k = P(N_k)-P(N_{k-1})$ for $k \geq 1$ be the atoms of $\mathcal{N}$. Then $T = \sum_{k \geq 1} \lambda_k A_k + T_\infty$ where $T_\infty = P(N_\infty)^{-1}T P(N_\infty)^{-1}$ is compact. It will be shown that $\lim_{k \to \infty} \lambda_k = \lambda_\infty$ exists. For otherwise, there is an $\epsilon > 0$ and a sequence $k_1 < k_2 < \ldots$ such that $|\lambda_{k_i} - \lambda_{k_{i+1}}| \geq \epsilon$. Let $e_i$ be a unit vector in $A_{k_i}.M$. Then $S = \sum_{i \geq 1} e_i \otimes e_{i+1}$ belongs to $\mathcal{T}(\mathcal{N})$. So
\[ \delta_T(S) = \sum_{i \geq 1} (\lambda_{k_i} - \lambda_{k_{i+1}})e_i \otimes e_{i+1}^* \]

This is not compact, contrary to hypothesis. So \( \lim \lambda_k \) must exist. Hence
\( K_1 = T - \lambda_{\infty} J \) is compact, and \( \delta = \delta_{K+K_1} \) is inner.

**Case 3.** \( \mathcal{N} \) contains an \( N_\infty \) of finite dimension, and
\[ \{ N \in \mathcal{N} : N > N_\infty \} = \{ ...N_k < ... < N_1 < N_0 = \mathcal{N} \} \]
is a decreasing sequence of subspaces of finite codimension with
\[ \bigwedge_{k \geq 1} N_k = N_\infty \] Then \( \delta_{T^*} \) is a derivation of \( T(\mathcal{N}^\perp) \) into \( K \), so \( T^* \) is scalar plus compact by case 2. Hence so is \( T \), and thus \( \delta \) is inner.

**Case 4.** \( \mathcal{N} \) is a finite nest consisting only of subspaces of finite dimension or codimension. Thus \( \mathcal{N} \) has one atom \( A \) such that \( A^\perp \) is finite rank. So \( T = \lambda A + A^\perp TA \), and hence \( T - \lambda J \) is compact. Again, \( \delta \) is inner.

It is readily verified that these four cases are exhaustive. \( \blacksquare \)

**19.13 Corollary.** The essential commutant of \( Q T(\mathcal{N}) \) is \( C I + K \).

A linear map \( T \) between Banach spaces \( X \) and \( Y \) is called **weakly compact** if \( T b_1(X) \) is weakly compact. This notion coincides with boundedness when \( X \) is reflexive. Now we classify those derivations of \( T(\mathcal{N}) \) which are compact or weakly compact.

**19.14 Theorem.** Let \( \delta = \delta_X \) be a derivation of \( B(\mathcal{N}) \) and let \( \mathcal{N} \) be a nest. The following are equivalent:

i) \( \delta \) is weakly compact,

ii) \( \delta \mid T(\mathcal{N}) \) is weakly compact,

iii) \( Ran(\delta) \) is contained in \( K \),

iv) \( Ran(\delta \mid T(\mathcal{N})) \) is contained in \( K \),

v) \( \delta = \delta_K \) for some \( K \) in \( K \).

**Proof.** Clearly i) implies ii). Now \( \delta \) maps \( K \) into itself. Let \( \delta_0 = \delta \mid K \cap T(\mathcal{N}) \) belong to \( B(\mathcal{K} \cap T(\mathcal{N}), K) \). By Theorem 16.7, \( (K \cap T(\mathcal{N}))^{**} = T(\mathcal{N}) \) and by Theorem 1.15, \( K^{**} = B(\mathcal{N}) \). A simple computation using the weak* continuity of \( \delta \) shows that \( \delta \mid T(\mathcal{N}) = \delta_0^{**} \). The image of the unit ball \( B_0 = \delta^{**}_0(\mathcal{K} \cap T(\mathcal{N})) \) is closed and convex, hence \( K \)-weakly closed in \( K \). Now \( B_0 \) is a subset of \( B = \delta^{**}_0(T(\mathcal{N})) \) which is \( B(\mathcal{N}) \)-weakly compact. The \( K \)-topology (or weak* topology) on \( B \) is a weaker Hausdorff topology, and thus must agree with the \( B(\mathcal{N}) \)-topology in \( B \). So \( B \) is \( K \)-compact and thus so is \( B_0 \). But the unit ball of any Banach space is weak* dense in the ball of its second dual (Goldstone's Theorem). Hence \( B_0 \) is \( K \)-dense in \( B \), whence \( B = B_0 \) is contained in \( K \).
This proves ii) implies iv). By Theorem 19.12, iv) implies v). Clearly, v) implies iii), and iii) implies iv).

Suppose \( \delta = \delta_F \) and \( F \) is finite rank; say \( F = PFP \) where \( P \) is a finite rank projection. Then \( \delta b_1(B(\mathcal{H})) \) is contained in \( ||F||b_1(PB(\mathcal{H})) + b_1(B(\mathcal{H})P) \). Now \( B(\mathcal{H})P \) is contained in \( K \), so the \( B(\mathcal{H}) \) and \( K \) topologies coincide. Clearly \( b_1(B(\mathcal{H})P) \) is weak* compact. Likewise \( b_1(PB(\mathcal{H})) \) is weakly compact, so \( \delta_F \) is weakly compact. Now if \( K \) is a compact operator, choose finite rank operators \( F_n \) converging to \( K \). Then \( \delta_K \) is the limit of \( \delta_{F_n} \), and hence is weakly compact. This established v) implies i).

19.15 Theorem. Let \( \mathcal{H} \) be a nest. Let \( N_f \) (and \( N_e \)) be the sup (inf) of all finite (cofinite) dimensional elements of \( \mathcal{H} \). Let \( \delta = \delta_X \) be a derivation of \( T(\mathcal{H}) \) onto \( B(\mathcal{H}) \). The following are equivalent:

i) \( \delta \) is compact,

ii) \( \delta = \delta_K \) where \( K = P(N_f)KP(N_e)^\perp \) is compact,

iii) \( \delta \) is the limit of finite rank derivations of \( T(\mathcal{H}) \) into \( T(\mathcal{H}) \cap K \).

Proof. Assume i) holds. Then \( \delta \) is weakly compact by Theorem 19.14, and hence \( \delta = \delta_K \) for some compact operator \( K \). Let \( N \) be an infinite dimensional element of \( \mathcal{H} \). If \( P(N)^\perp K \neq 0 \), choose a unit vector \( y \) in \( N^\perp \) such that \( K^*y \) is not a multiple of \( y \). Let \( Q \) be the orthogonal projection onto \( \mathcal{C} y \). For every unit vector \( x \) in \( N \), \( x \otimes y^* \) belongs to \( b_1(T(\mathcal{H})) \) by Proposition 2.8. Now

\[
\delta_K(x \otimes y^*)Q^\perp = (Kx \otimes y^* - x \otimes (K^*y)^*)Q^\perp = -x \otimes (Q^\perp K^*y)^* .
\]

Since \( Q^\perp K^*y \neq 0 \), and \( N \) has infinite dimension, \( b_1(T(\mathcal{H})) \) is not compact. So i) implies that \( P(N_\perp)^\perp K = 0 \) or \( K = P(N_e)K \). The infimum of all infinite dimensional elements of \( \mathcal{H} \) is clearly \( N_f \) if \( \dim N_f = \infty \) or \( N_f^+ \) otherwise. In either case, \( \inf\{N_\perp: \dim N = \infty, N \in \mathcal{H} \} = N_f \). So \( K = P(N_f)K \). Either by considering \( \delta^* \) on \( T(\mathcal{H})^\perp \) or by essentially repeating the argument above, one obtains \( K = P(N_f)KP(N_e)^\perp \). This shows i) implies ii).

There are finite dimensional elements \( N_k \) in \( \mathcal{H} \) such that \( P(N_k) \) converges strongly* to \( P(N_f) \). Similarly, there are cofinite elements \( M_k \) with \( P(M_k) \) converging strongly* to \( P(N_e) \). By Proposition 1.18, \( F_k = P(N_k)KP(M_k)^\perp \) converges in norm to \( K \). For \( T \) in \( T(\mathcal{H}) \),

\[
\delta_{F_k}(T) = P(N_k)KP(M_k)^\perp T - TP(N_k)KP(M_k)^\perp
\]

\[
= P(N_k)\delta_{F_k}(T)P(M_k)^\perp .
\]
This has range in the finite dimensional space $P(N_h) B (\mu) P(M_h)^\perp$, which is contained in $T(\mu) \cap \mathcal{K}$. As $\delta_{F_h}$ converge to $\delta_{\mathcal{K}}$, ii) implies iii). Finally, iii) implies i) trivially.

Next, we will show that a sequence of derivations converging point-wise in fact converges in the norm. This result is akin to the well-known result that a sequence in $\ell_1$ which converges weakly must converge in norm. Indeed, our first lemma is a strengthening of this fact. (A proof using it is sketched in Exercise 19.3).

**19.16 Phillip's Lemma.** Let $\phi_n$ be a sequence in $\ell^*_\infty$ which converges to 0 in the weak* topology. Then $\|\phi_n|c_0\| = \sum_{k=1}^{\infty} |\phi_n(e_k)|$ converges to zero. ($e_k$ is the standard basis for $c_0$).

**Proof.** Suppose that $\limsup_{n \to \infty} |\phi_n|c_0\| > \epsilon > 0$. Now $\lim_{n \to \infty} \phi_n(e_k) = 0$ for every $k \geq 1$. Iteratively choose increasing sequences of integers $0 < N_1 < N_2 < ...$ and $0 < n_1 < n_2 < ...$ such that $\|\phi_{n_k}|c_0\| > \epsilon$ and

$$\sum_{i=1}^{N_{k-1}} |\phi_{n_k}(e_i)| + \sum_{i > N_k} |\phi_{n_k}(e_i)| < \epsilon/4 . \quad (*)$$

Once $N_1, ..., N_k$ and $n_1, ..., n_k$ are defined, choose $n_{k+1}$ so large that

$$\sum_{i=1}^{N_k} |\phi_{n_{k+1}}(e_i)| < \epsilon/4$$

and $\|\phi_{n_{k+1}}|c_0\| > \epsilon$. Now choose $N_{k+1}$ large enough that (*) holds. Let $B_k$ denote the interval $\{i: N_k < i \leq N_k\}$.

If $\Sigma$ is a subset of $\mathbb{N}$, let $||\phi|\Sigma|| = \sup \{|\phi(x)| : x \in \ell_\infty, ||x||\leq 1, \supp(x) \leq \Sigma\}$. The next step is to produce a subsequence $k_1, k_2, ...$ so that

$$||\phi_{n_{k_i}} \bigcup_{j \in \delta} B_j|| < \epsilon/4 \ .$$

Take $k_1 = 1$. Split $\mathbb{N}\setminus\{1\}$ into disjoint infinite sets $\Delta_1, \Delta_2, ...$. Let $\Sigma_i = \bigcup_{j \in \Delta_i} B_j$. At most $M = 4||\phi_n||\epsilon^{-1}$ of these have $||\phi_n|\Sigma_i|| \geq \epsilon/4$. To see this, choose $x_i$ with support $\Sigma_i$, $||x_i|| = 1$, and $\phi_n(x_i) \geq \epsilon/4$ for $i$ in a set $I$ of cardinality at least $M+1$. Let $x = \sum_{i \in I} x_i$. Then $||x|| = 1$ and

$$\phi_n(x) = \Sigma_{I} \phi_n(x_i) > (M+1)\epsilon/4 > ||\phi_n|| .$$

So one obtains infinite subsets $\Delta$ and $\Sigma = \bigcup_{j \in \Delta} B_j$ so that $||\phi_n|\Sigma|| < \epsilon/4$.

Consider the subsequence $k_1 \cup \Delta$. Pick $k_2$ in $\Delta$ and proceed as above to obtain an infinite subset $\Delta_2$ of $\Delta$ and $\Sigma_2 = \bigcup_{j \in \Delta_2} B_j$ so that $||\phi_{n_{k_2}}|B_{k_1} \cup \Sigma_2|| < \epsilon/4$. Proceeding iteratively, one obtains the desired
subsequence. For convenience, let us relabel this subsequence as $\phi_1, \phi_2, \ldots$
and corresponding sets $B_1, B_2, \ldots$.
From $\| \phi_i |c_0\| > \epsilon$ and ($*$), one has $\| \phi_i |B_i\| > 3\epsilon / 4$. Choose $x_i$ on $\ell_\infty$ with $\text{supp}(x_i)$ contained in $B_i$, $\| x_i \| = 1$, and $\phi_i(x_i) > 3\epsilon / 4$. Let $x = s - \sum_{i \geq 1} x_i$. Then $\text{supp}(\sum_{j \neq i} x_j)$ is contained in $\Sigma_i = \bigcup_{j \neq i} B_j$ and hence
\[
\phi_i(x) > \phi_i(x_i) - |\phi_i(\sum_{j \neq i} x_j)| > 3\epsilon / 4 - \| \phi_i |\Sigma_i\| > \epsilon / 2 .
\]
This contradicts the fact that $\lim \phi_i(x) = 0$. So the lemma must be valid. ■

19.17 Lemma. Let $\delta_n$ be a sequence of derivations from a von Neumann algebra $A$ into $B (\mathcal{H})$ such that $\lim_{n \to \infty} \delta_n(A) = 0$ for all $A$ in $\mathcal{A}$. If $P$ and $Q$ are mutually orthogonal projections in the centre $Z(A)$, then
\[
\limsup \| \delta_n [(P + Q)A] \| = \max \{ \limsup \| \delta_n |PA\|, \limsup \| \delta_n |QA\| \}.
\]

Proof. For all $A$ in $\mathcal{A}$,
\[
\delta_n(PA) = \delta_n(PPAP) = \delta_n(P)PA + P\delta_n(PA)P + P\delta_n(P) .
\]
Since $\lim_{n \to \infty} \| \delta_n(P) \| = 0$, one obtains $\lim_{n \to \infty} \| \delta_n(PA) - P\delta_n(PA)P \| = 0$ uniformly for $\| A \| \leq 1$. Similarly, this holds for $Q$. Since
\[
\| PAP + QBQ \| = \max \{ \| PAP \|, \| QBQ \| \} ,
\]
on one obtains for $\| A \| \leq 1$,
\[
\limsup \| \delta_n ((P + Q)A) \| = \limsup \| \delta_n(PA) + \delta_n(QA) \|
\]
\[
= \limsup \| P\delta_n(PA)P + Q\delta_n(QA)Q \|
\]
\[
= \limsup \max \{ \| P\delta_n(PA)P \|, \| Q\delta_n(QA)Q \| \}
\]
\[
\leq \max \{ \limsup \| \delta_n |PA\|, \limsup \| \delta_n |QA\| \}.
\]
The reverse inequality is immediate. ■

19.18 Theorem. Let $A$ be an abelian von Neumann algebra, and suppose $\delta_n$ is a sequence of derivations converging pointwise to zero. Then $\lim_{n \to \infty} \| \delta_n \| = 0$.

Proof. By the Uniform Boundedness Principle, $\sup \| \delta_n \| < \infty$. So we will suppose that $\| \delta_n \| \leq 1$. Assume that $\limsup \| \delta_n \| > \epsilon > 0$. We will choose a sequence $n_1 < n_2 < \ldots$ and pairwise orthogonal projections $P_1, P_2, \ldots$ in $\mathcal{A}$ so that $\| \delta_{n_k}(P_k) \| > \epsilon / 8$. Assume $P_1, \ldots, P_k$ have been chosen,
and let $Q_k = (\sum_{i=1}^{k} P_i)$. Furthermore, we also assume that
\[
\limsup_{n \to \infty} \|\delta_n \| Q_k A \| > \epsilon. \tag{1}
\]
Then choose $n_{k+1} > n_k$ large enough so that $\|\delta_{n_{k+1}} - Q_k A \| > \epsilon$ and $\|\delta_{n_{k+1}}(Q_k A)\| < \epsilon/8$. Since the convex combinations of projections in $Q_k A$ are norm dense in the positive cone, there is a projection $P < Q_k$ so that $\|\delta_{n_{k+1}}(P)\| > \epsilon/4$. Thus $\|\delta_{n_{k+1}}(Q_k - P)\| > \epsilon/8$. By Lemma 19.17, either $\limsup_{n \to \infty} \|\delta_n \| PA \| > \epsilon$ or $\limsup_{n \to \infty} \|\delta_n \| (Q_k - P) A \| > \epsilon$. Take $P_{k+1}$ to be the other projection, $(Q_k - P)$ or $P$ respectively. Then
\[
\|\delta_{n_{k+1}}(P_{k+1})\| > \epsilon/8 \quad \text{and} \quad \limsup_{n \to \infty} \|\delta_n \| Q_k A \| > \epsilon. \tag{2}
\]
The sequences $n_k$ and $P_k$ are now produced inductively.

Now choose norm one linear functionals $f_k$ on $B(\mathcal{H})$ so that $f_k(\delta_{n_k}(P_k)) > \epsilon/8$. Define $\phi_k$ in $\ell^{\infty}$ by
\[
\phi_k(x_n) = f_k(\delta_{n_k}(\sum_{n=1}^{\infty} x_n P_n)). \tag{3}
\]
Then $\|\psi_k\| \leq \|f_k\| \|\delta_{n_k}\| \leq 1$. For each $x$ in $\ell^{\infty}$ and $A = \sum_{n=1}^{\infty} x_n P_n$,
\[
\lim_{n \to \infty} \psi_k(x) = \lim_{n \to \infty} f_k(\delta_{n_k}(A)) = 0. \tag{4}
\]
So $\phi_k$ converge weak* to 0. By Phillips' Lemma 19.16, $\|\phi_k \| e_0\|$ tends to 0. But $\phi_k(e_k) = f_k(\delta_{n_k}(P_k)) > \epsilon/8$. This contraction establishes the theorem.

**19.19 Lemma.** Let $\delta_n$ be a sequence of derivations on $B(\mathcal{H})$, where $\mathcal{H}$ is a Hilbert space of finite or infinite dimension, which converges pointwise to zero. Then $\lim_{n \to \infty} \|\delta_n\| = 0$.

**Proof.** By Theorem 10.8, $\delta_n = \delta X_n$ for $X_n$ in $B(\mathcal{H})$. Fix a unit vector $e_0$ and add a scalar multiple of the identity to $X_n$ so that $(X_n e_0, e_0) = 0$. For every vector $x$ in $\mathcal{H}$,
\[
[X_n x \otimes e_0] e_0 = X_n x (e_0, e_0) - x (X_n e_0, e_0) = X_n x. \tag{5}
\]
This converges to zero. Likewise, $e_0^*[X_n x \otimes x^*] = -(X^* x)^*$ converges to zero. Thus $X_n$ converges to 0 in the strong topology. If $\mathcal{H}$ is finite dimensional, $X_n$ converges to 0 in norm. So we will suppose that $\mathcal{H}$ is infinite dimensional.

Suppose that $\limsup \|X_n\| = \epsilon > 0$. One can choose a subsequence $n_1 < n_2 < \ldots$ and an orthonormal set $e_0, e_1, e_2, \ldots$ so that $\|X_{n_k} e_k\| > \epsilon/2$ and $\|X_{n_k} e_{n_k}\| < \epsilon/4$. To see this, suppose $e_0, \ldots, e_k, n_1, \ldots, n_k$ are chosen. Take $N$ so large that
\[ \|X_n \text{ span } \{e_0, \ldots, e_k\}\| < \epsilon/4 \text{ for } n \geq N. \]

Then choose \( n_k \geq N \) so \( \|N_{n_k}\| > 3\epsilon/4 \) and note that
\[ \|X_{n_k} \text{ span } \{e_0, \ldots, e_k\}\| > \epsilon/2. \]
Choose \( e_{k+1} \) appropriately, and proceed iteratively. Now set \( A = \sum_{k=1}^{\infty} e_k \otimes e_{k-1}^* \). Then
\[ \|\delta_n(A)e_{k-1}\| = \|X_{n_k} Ae_{k-1} - AX_{n_k} e_{k-1}\| \geq \|X_{n_k} e_k\| - \|X_{n_k} e_{k-1}\| > \epsilon/4. \]
This contradicts \( \lim_{n \to \infty} \|\delta_n(A)\| = 0 \). So \( \lim_{n \to \infty} \|X_n\| = 0 \) follows.

**19.20 Theorem.** Let \( \mathcal{A} \) be a von Neumann algebra with abelian commutant. Let \( \delta_n \) be a sequence of derivations into \( B(\mathcal{N}) \) converging pointwise to zero. Then \( \lim_{n \to \infty} \|\delta_n\| = 0 \).

**Proof.** By Theorem 19.8, the restriction \( \delta_n' \) of \( \delta_n \) to \( \mathcal{A}' \) converges to zero in norm. By Theorem 19.8, \( \delta_n' = \delta_n X_n \) where by Theorem 9.6, \( \text{dist}(X_n, \mathcal{A}') \leq \|\delta_n'\| \). So it may be supposed that \( \|X_n\| \) tends to zero. Replace \( \delta_n \) by \( \delta_n = \delta_n - \delta X_n \), and now one has a sequence of derivation converging pointwise to zero such that \( \delta_n | \mathcal{A}' = 0 \). So if \( A \) belongs to \( \mathcal{A} \) and \( B \) to \( \mathcal{A}' \), then
\[ B\delta_n(A) = \delta_n(AB) = \delta_n(BA) = \delta_n(A)B. \]
Thus \( \delta_n \) maps \( \mathcal{A} \) into itself. If \( P \) and \( Q \) are mutually orthogonal projections in \( \mathcal{A}' \) and \( A = AP \) and \( B = BQ \) are norm one elements of \( \mathcal{A} \), then
\[ \delta_n(A+B) = P\delta_n(A)P+Q\delta_n(B)Q. \]
So \( \|\delta_n [(P+Q)A]\| \geq \max \{ \|\delta_n [PA]\|, \|\delta_n [QA]\| \}. \)

If \( \limsup \|\delta_n\| > 0 \), drop to a subsequence and normalize so that the sequence, say \( \delta_{n_1} \), satisfies \( \|\delta_{n_1}\| = 1 \). It still converges pointwise to 0, and vanishes on \( \mathcal{A}' \). Let \( \mathcal{E} \) be a maximal chain of projections in \( \mathcal{A}' \) such that \( \limsup \|\delta_{n_1}[EA]\| = 1 \), and let \( E_0 = \inf \{E : E \in \mathcal{E} \} \). If \( E_0 \) belongs to \( \mathcal{E} \), then \( E_0 \) is not an atom of \( \mathcal{A}' \) for then \( E_0 \mathcal{A} = B(E_0) \) contradicting Lemma 19.19. So \( E_0 = E_1 + E_2 \) where \( E_1 \) and \( E_2 \) are non-zero projections in \( \mathcal{A} \). But then
\[ 1 = \lim_{n \to \infty} \sup \|\delta_n | E_0 A\| \]
\[ = \lim_{n \to \infty} \sup \max \{ \|\delta_n | E_i A\| \} = \max \{ \lim_{n \to \infty} \sup \|\delta_n | E_i A\| \}. \]
So either \( E_1 \) or \( E_2 \) belongs to \( \mathcal{E} \), contradicting maximality. Thus \( E_0 \) is not in \( \mathcal{E} \). For \( E \) in \( \mathcal{E} \), \( \|\delta_n | E A\| = \max \{ \|\delta_n | EE_0 E^\perp A\|, \|\delta_n | E_0 A\| \} \). Since \( \limsup \|\delta_n | E_0 A\| < 1 \), it follows that \( \limsup \|\delta_n | E E_0 E^\perp A\| = 1 \). Let \( \mathcal{E}_0 = \{ E E_0 E^\perp : E \in \mathcal{E} \} \) and note that \( \inf \{E : E \in \mathcal{E}_0 \} = 0 \).
By Theorem 10.3, $\delta_n$ is weak* continuous. So if $F$ belongs to $E_0$, then $\sup_{E \in E_0} \|\delta_n (F-E)A\| = \|\delta_n FA\|$. Choose a subsequence $n_1 < n_2 < ...$ and projections $E_0 > E_1 > ...$ in $E_0$ so that $\|\delta_{n_k} (E_{i-1}-E_i)A\| > \frac{\eta}{4}$. To achieve this, suppose $n_1, ..., n_k$ and $E_1, ..., E_k$ are defined. Choose $n_{k+1} > n_k$ so that $\|\delta_{n_{k+1}} E_k A\| > \frac{\eta}{4}$. Then by the sentence above, one can choose $E_{k+1}$ in $E_0$ so that $\|\delta_{n_{k+1}} (E_{k-1}-E_{k+1})A\| > \frac{\eta}{4}$. Let $A_k = A_k (E_{k-1}-E_k)$ be norm one elements of $A$ so that $\|\delta_{n_k} (A_k)\| > \frac{\eta}{4}$. Let $A = A - \sum_{k \geq 1} A_k$. Then $A$ belongs to $A$, and

$$\|\delta_{n_k} (A)\| \geq \|\delta_{n_k} (A_k)\| = \|\delta_{n_k} (A_k)\| > \frac{\eta}{4}$$

contradicting pointwise convergence. Hence $\lim_{n \to \infty} \|\delta_n\| = 0$ follows.

19.21 Theorem. Let $\mathcal{N}$ be a nest, and let $\delta_n$ be a sequence of derivations of $\mathcal{T} (\mathcal{N})$ onto $B (\mathcal{N})$ which converge pointwise to $0$. Then $\lim \|\delta_n\| = 0$.

Proof. The restriction $\delta'_n$ of $\delta_n$ to $\mathcal{N}$ converge to $0$ in norm by Theorem 19.20. By Theorem 10.8 and 9.6, $\delta'_n = \delta \chi_n$ with $\|\chi_n\| \leq \|\delta_n\|$. So $\delta_n = \delta_n - \delta \chi_n$ also converges to $0$ pointwise, and $\delta_n | \mathcal{N} = 0$. By Proposition 19.11, $\delta_n = \delta \chi_n$ and thus $Y_n$ belongs to $\mathcal{N}$. If $\limsup \|\delta_n\| > \epsilon > 0$, drop to a subsequence labelled $\delta_n = \delta \chi_n$, so that $\|\delta_n\| > \epsilon$ for all $n \geq 1$. So $\text{dist} (Y_n, \mathcal{N}) > \epsilon / 2$.

If $\mathcal{N}$ has atoms, fix one atom $A_0 = P(N_i) - P(N_0)$. Without loss of generality, it may be assumed that $Y_n A_0 = 0$. If $e$ is a unit vector in $N_i$ and $e_0 = A_0 e_0$, then $T = e \otimes e_0^*$ belongs to $\mathcal{T} (\mathcal{N})$. So

$$0 = \lim_{n \to \infty} \|\delta_n (T) e_0\| = \lim_{n \to \infty} \|Y_n e\| .$$

Similarly, one obtains $\lim_{n \to \infty} \|Y_n e\| = \lim_{n \to \infty} \|Y_n e^*\| = 0$ for $e$ in $N_i$. So $Y_n$ tends strongly to $0$, and in particular $\lim_{n \to \infty} \|Y_n A\| = 0$ for every atom $A$. Let $E$ be the sum of all atoms and suppose that $\limsup \|Y_n E\| > \eta > 0$. As in Lemma 19.19, find a subsequence $n_1 < n_2 < ...$ and distinct atoms $A_k$ so that $\|Y_{n_k} A_k\| > \eta$ and $\|Y_{n_k} A_{k-1}\| < \eta / 2$. Pick unit vectors $e_k$ in $A_k \mathcal{N}$, and let $T_k = e_{2k-1} \otimes e_{2k}^*$ if $A_{2k-1} \ll A_{2k}$ or $T_k = e_{2k} \otimes e_{2k-1}^*$ if $A_{2k} \ll A_{2k-1}$. Set $T = \sum_{k=1}^{\infty} T_k$. A computation shows that

$$\|\delta_{n_{2k}} (T)\| \geq \|(A_{2k-1} + A_{2k}) \delta_{n_{2k}} (T)\| = \|\delta_{n_{2k}} (T_k)\| > \eta / 2 .$$

This contradiction establishes $\lim_{n \to \infty} \|Y_n E\| = 0$. 

Derivations 279
If \( \mathcal{N} \) is not atomic yet has an atom, it follows that \( Y_n E^{\perp} \) tends strongly to 0 but \( \|Y_n E^{\perp}\| > \varepsilon/2 \). So it can and will be assumed that \( Y_n E^{\perp} \) is not bounded below by \( \varepsilon/4 \). On the other hand, if \( \mathcal{N} \) is nonatomic, \( Y_n \) can be assumed to be non-invertible and \( \|Y_n E^{\perp}\| > \varepsilon/2 \). For each \( n \), choose non-zero projections \( E_n \) and \( F_n \) in \( \mathcal{N}E^{\perp} \) so that \( \|Y_n E_n\| < \varepsilon/4 \) and \( Y_n F_n \) is bounded below by \( \varepsilon/2 \) on \( F_n \). One can choose \( N_n \) in \( \mathcal{N} \) so that either \( E_n P(N_n) \neq 0 \) and \( F_n P(N_n)^{\perp} \neq 0 \) or \( E_n P(N_n)^{\perp} \neq 0 \) and \( F_n P(N_n) \neq 0 \). Without loss of generality, the first case occurs infinitely often and by dropping to a subsequence, it occurs always. Let \( \mu \) be a continuous scalar valued measure absolutely continuous to \( \mathcal{N}E^{\perp} \), and let \( \mu(S) \) denote the \( \mu \)-measure of the corresponding Borel set \( S \). Choose non-zero projections \( E_n' \) and \( F_n' \) in \( \mathcal{N}' \) so that (i) \( E_n' \leq E_n P(N_n) \), \( F_n' \leq F_n P(N_n)^{\perp} \), (ii) \( \mu(E_n') = \alpha_n \), \( \mu(F_n') = \beta_n \), and (iii) \( \alpha_{n+1} < \alpha_n /3 \) and \( \beta_{n+1} < \beta_n /3 \). Then \( E_n'' = E_n'(\sum_{k=1}^{n} E_k')^{\perp} \) and \( F_n'' = F_n'(\sum_{k=1}^{n} F_k')^{\perp} \) are non-zero, and \( \{E_n''\} \) and \( \{F_n''\} \) are pairwise orthogonal projections. Pick unit vectors \( e_n = E_n'' e_n \) and \( f_n = F_n'' f_n \). Then \( \sum_{n=1}^{\infty} e_n \otimes f_n^* \) belongs to \( T(\mathcal{N}) \). So

\[
\|\delta_n(T)\| \geq \|E_n'' \delta_n(T) F_n''\| = \|Y_n e_n \otimes f_n^* - e_n \otimes (Y_n f_n)^*\|
\geq \|Y_n f_n\| - \|Y_n e_n\| = \|Y_n f_n\| - \|Y_n e_n\|
> \varepsilon/2 - \varepsilon/4 = \varepsilon/4 .
\]

This contradiction implies that \( \lim_{n \to \infty} \|Y_n E^{\perp}\| = 0 \), and hence \( \lim_{n \to \infty} \|Y_n\| = 0 \).

Appendix: \( K_0 \) of a Nest Algebra.

\( K \) theory is a generalized homology theory for Banach algebras which extends the corresponding notions from algebraic topology. Its main significance has been its use as an isomorphism invariant to distinguish certain \( C^* \)-algebras. (Eg. AF \( C^* \)-algebras and irrational rotation algebras.) The interested reader can consult Taylor [1] for a nice introduction to \( K \) theory of Banach algebras, and Blackadar [1] for a full treatment of \( K \) theory for \( C^* \)-algebras and many references. The computation of \( K_0 \) of a nest algebra, which we present here, is due to Pitts [2].

Let \( \mathcal{A} \) be a unital Banach algebra, and let \( \mathcal{M}_n(\mathcal{A}) \) denote the algebra of \( n \times n \) matrices with coefficients in \( \mathcal{A} \). Let \( P_n(\mathcal{A}) \) denote the set of all idempotents in \( \mathcal{M}_n(\mathcal{A}) \). For \( n < m \), imbed \( P_n(\mathcal{A}) \) into \( P_m(\mathcal{A}) \) by sending an idempotent \( E \) to \( E \oplus O_{m-n} \), where \( O_{m-n} \) is the zero matrix in \( \mathcal{M}_{m-n}(\mathcal{A}) \). An equivalence relation \( \sim \) is put on \( \bigcup_{n=1}^{\infty} P_n(\mathcal{A}) \) by setting \( E \sim F \) if there are integers \( r \), \( s \) and \( n \) such that \( E \oplus O_r \) and \( F \oplus O_s \) are similar in \( \mathcal{M}_n(\mathcal{A}) \). Let \( S(\mathcal{A}) \) denote the set of equivalence classes. The equivalence class of \( E \) will be denoted by \([E]\). An addition is defined on
Derivations

\[ S(A) \]

by

\[ [E] + [F] = [E \oplus F] \]

This is easily seen to be well defined, and makes \( S(A) \) into an abelian monoid with \([0]\) as a neutral element.

\( K_0(A) \) is the abelian group obtained from \( S(A) \) by introducing formal inverses and the cancellation law. Formally, this is done by considering all pairs \((a,b), (c,d), \) etc. in \( S(A) \times S(A) \). Define \( (a,b) + (c,d) = (a+c, b+d) \). Then introduce an equivalence relation \( (a,b) \sim (c,d) \) if there is an element \( e \) in \( S(A) \) such that \( a + d + e = b + c + e \). It is routine to verify that the set of equivalence classes \( \{a,b\} \) forms an abelian group, called \( K_0(A) \). For example, \( \{b,a\} \) is the inverse of \( \{a,b\} \). If \( S(A) \) satisfies cancellation, meaning that \( a + c = b + e \) implies \( a = b \), then the map taking \( a \) to \( \{a,0\} \) is an injective homomorphism of \( S(A) \) into \( K_0(A) \). Otherwise, this does not hold.

If \( \phi \) is a continuous homomorphism of a unital Banach algebra \( A \) onto another unital algebra \( B \), then \( \phi \) induces a natural homomorphism \( \phi^{(n)} \) of \( M_n(A) \) into \( M_n(B) \). This determines a map of \( \bigcup P_n(A) \) into \( \bigcup P_n(B) \). If \( E \) and \( F \) are similar in \( M_n(A) \) via \( S \), then \( \phi^{(n)}(E) \) is similar to \( \phi^{(n)}(F) \) via \( \phi^{(n)}(S) \). Therefore, \( \phi \) induces a homomorphism of \( S(A) \) into \( S(B) \). This uniquely determines a homomorphism \( \phi_* \) of \( K_0(A) \) into \( K_0(B) \). Suppose \( \phi \) is a homomorphism of \( B \) into \( C \). It is routine to verify that \( \psi \circ \phi \circ \psi^{-1} \) is also a homomorphism.

The first lemma shows that algebras which are “infinite” have trivial \( K \)-theory because of cancellation.

19.22 Lemma. Let \( A \) be a unital, weak* closed subalgebra of \( B(H) \). Then \( K_0(A \otimes B(H)) = 0 \).

Proof. First note that \( M_n(A \otimes B(H)) \cong A \otimes B(H) \). So it suffices to show that every idempotent \( E \) in \( A \otimes B(H) \) has \( [E] = [0] \). Now \( A \otimes B(H) \cong A \otimes B(H) \otimes B(H) \), and the latter algebra can be thought of as infinite matrices with coefficients in \( A \otimes B(H) \). In particular, the diagonal matrix \( E^{\text{id}} \) belongs to this algebra. We exhibit it in \( A \otimes B(H) \) explicitly as follows. Let \( W_n, n \geq 1 \), be a sequence of isometries in \( B(H) \) with pairwise orthogonal ranges such that \( \sum_{n \geq 1} W_n^* W_n = I \) in the strong operator topology. Then \( W_n = I \otimes \tilde{W}_n \) are isometries in \( A \otimes B(H) \) with the same property. Let

\[ F = \sum_{n \geq 1} W_n E W_n^* \]

This converges SOT and thus is an idempotent in \( A \otimes B(H) \) unitarily
equivalent to $E^{(\mathcal{D})}$.

Let $S$ denote the shift operator taking the $n$-th "copy" of $E$ to the $(n+1)$st for all $n \geq 1$. Precisely, $S = \sum_{n \geq 1} W_{n+1} W_n^*$. Note that

$$F - SF S^* = \sum_{n \geq 1} W_n E W_n^* - \sum_{n \geq 2} W_n E W_n^* = W_1 EW_1^*.$$ 

Also let $V_1$ and $V_2$ be isometries of $B(H)$ with $V_1 V_1^* + V_2 V_2^* = I$. Set $V_i = I \otimes V_i$, which are isometries in $A \otimes B(H)$ with the same property.

Note that

$$\begin{bmatrix} W_1 & S & 0 \\ 0 & 0 & V_2 \\ 0 & 0 & V_2 \end{bmatrix}$$

is a unitary operator in $M_3(A \otimes B(H))$. Moreover,

$$\begin{bmatrix} 0 & 0 & V_1^* \\ W_1 & S & 0 \\ 0 & 0 & V_2 \end{bmatrix} \begin{bmatrix} E & 0 & 0 \\ 0 & W_1^* & 0 \\ 0 & 0 & S^* \end{bmatrix} \begin{bmatrix} W_1 & S & 0 \\ 0 & 0 & V_2 \\ 0 & 0 & V_2 \end{bmatrix} = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}$$

It follows that $[E] + [F] + [0] = [F] + [0]$. Hence $[E] = [0]$. But $E$ is arbitrary, so $K_0(A \otimes B(H)) = 0$.

**19.23 Corollary.** Let $\mathcal{N}$ be a continuous nest. Then $K_0(T(\mathcal{N})) = 0$.

**Proof.** By Theorem 13.10, every continuous nest is similar to a nest of uniform infinite multiplicity (see Example 13.11). Let $\mathcal{M}_0 = \mathcal{N} \otimes I$ be the infinite ampliation of $\mathcal{N}$, and let $S$ be an invertible operator implementing a similarity. Then $T(\mathcal{N})$ is similar to $T(\mathcal{M}_0) \simeq T(\mathcal{N}) \otimes B(H)$. Thus by Lemma 19.22, $K_0(T(\mathcal{N})) = 0$.

Let $\mathcal{N}_0$ be a nest, and let $\Delta$ be the unique expectation onto the atomic part $D_+(\mathcal{N}_0)$ of the diagonal. Let $S$ be any invertible operator, let $\mathcal{M}_1 = S \mathcal{M}_0$, and let $\Delta_1$ be the corresponding expectation onto $D_+(\mathcal{M}_1)$. Let $P_0 = \Delta(I)$ and $P_1 = \Delta_1(I)$. Since $\theta_S$ preserves dimension, one can choose a partial isometry $W$ which carries each atom $A$ onto $\theta_S(A)$ such that $W^* W = P_0$ and $W W^* = P_1$.

**19.24 Lemma.** Let $\mathcal{N}_0$, $\mathcal{N}_1$, $S$ and $W$ be given above. Let $E$ be any idempotent in $T(\mathcal{N})$ such that $E = EP_0 = P_0 E$. Then $[E] = [S^{-1} W E W^* S]$. 

Proof. Note that $WS$ and $S^{-1}W$ belong to $\mathcal{M}(\mathcal{N})$. A simple computation shows that
\[
\begin{bmatrix}
S^{-1}W & S^{-1}(I-P_1)S \\
P_0-I & W^*S
\end{bmatrix} \quad \text{and} \quad \begin{bmatrix}
WS & P_0-I \\
S^{-1}(I-P_1)S & S^{-1}W
\end{bmatrix}
\]
are inverses in $\mathcal{M}_d(\mathcal{M}(\mathcal{N}))$. Furthermore,
\[
\begin{bmatrix}
S^{-1}W & S^{-1}(I-P_1)S \\
P_0-I & W^*S
\end{bmatrix} \begin{bmatrix}
E & 0 \\
0 & 0
\end{bmatrix} \begin{bmatrix}
WS & P_0-I \\
S^{-1}(I-P_1)S & S^{-1}W
\end{bmatrix} = \begin{bmatrix}
S^{-1}WEW^*S & 0 \\
0 & 0
\end{bmatrix}.
\]
Thus $[E] = [S^{-1}WEW^*S]$ as claimed.

19.25 Theorem. Let $\mathcal{N}$ be a nest on a separable Hilbert space. Let $D_f(\mathcal{N})$ denote the atomic part of the diagonal algebra corresponding to finite rank atoms; and let $\Delta_f$ be the unique expectation onto $D_f(\mathcal{N})$. Then $\Delta_f$ is an isomorphism of $K_0(\mathcal{M}(\mathcal{N}))$ onto $K_0(D_f(\mathcal{N}))$.

Proof. Let $i$ be the injection of $D_f(\mathcal{N})$. Then $\Delta_f \circ i = id$, and hence
\[
\Delta_f \circ i_* = id_{K_0(D_f(\mathcal{N}))}.
\]
It will be shown that $i_* \circ \Delta_f = id_{K_0(D_f(\mathcal{N}))}$. To do this, it suffices to show that $[E] = [\Delta_f(E)]$ in $K_0(D_f(\mathcal{N}))$ for all idempotents $E$ in $M_n(\mathcal{M}(\mathcal{N}))$. Since $M_n(\mathcal{M}(\mathcal{N})) \cong \mathcal{M}(\mathcal{M}^n)$ and $\Delta_f$ is the diagonal expectation in $\mathcal{M}(\mathcal{M}^n)$, it suffices to verify this for $n = 1$.

Let $E$ be any idempotent in $\mathcal{M}(\mathcal{N})$. Let $X$ be any invertible operator such that $SES^{-1} = F = F^*$ is a projection. For example,
\[
S = (E^*E + (I-E)^*(I-E))^{\frac{1}{2}}
\]
will suffice. Let $\mathcal{N}_1 = S\mathcal{N}$, and let $\Delta$ and $\Delta_1$ be the expectations onto the atomic part of the diagonal (including infinite rank atoms). Since $Ad S$ is an isomorphism of $\mathcal{M}(\mathcal{N})$ onto $\mathcal{M}(\mathcal{N}_1)$, $\sigma_S = (Ad S)_*$ is an isomorphism on the $K_0$ groups. The projection $F$ is self-adjoint and thus $F = \Delta_1(F) + (F - \Delta_1(F))$ splits into its atomic and nonatomic part. The restriction $\mathcal{N}_1$ of $\mathcal{N}$ to $P_1^+\mathcal{N}$ is a continuous nest, and $F - \Delta_1(F) = P_1^+F$ identified with the restriction $F_e$ of $F$ to $P_1^+\mathcal{N}$. By Corollary 19.23, $K_0(\mathcal{M}(\mathcal{N}_1)) = 0$ and thus $[F_e] = 0$ in $K_0(\mathcal{M}(\mathcal{N}_1))$. Let $j$ be the injection of $\mathcal{M}(\mathcal{N}_1)$ onto $\mathcal{M}(\mathcal{N})$. Then it is easy to see that $0 = j_*[F_e] = [P_1^+F]$ in $K_0(\mathcal{M}(\mathcal{N}))$. Hence
\[
\sigma_S([E]) = [F] = [\Delta_1(F)].
\]
Let $W$ be a partial isometry as in Lemma 19.23 which carries the atoms of $\mathcal{N}$ onto the atoms of $\mathcal{N}_1$. By that lemma,
\[ \sigma_S[\Delta(E)] = \sigma_S[S^{-1}W\Delta(E)W^*S] = [W\Delta(E)W^*]. \]

The idempotent \( W\Delta(E)W^* \) belongs to \( D_\sigma(\mathcal{N}_i) \). Moreover, it is similar in \( D_\sigma(\mathcal{N}_i) \) to \( F \). To see this, let \( T = \Delta_i(SW^*) \) and note that \( \Delta_i(WS^{-1}) \) is its inverse in \( D_\sigma(\mathcal{N}_i) \). Then

\[ TW\Delta(E)W^*T^{-1} = \Delta_i(SW^*)\Delta_i(W\Delta(E)W^*)\Delta_i(SWS^{-1}) = \Delta_i(S\Delta(E)S^{-1}) = \Delta_i(SES^{-1}) = \Delta_i(F). \]

To verify the last line, check it on each atom. The computation is identical to the proof of Lemma 17.16.

Consequently, \( \sigma_S([\Delta(E)]) = \sigma_S([E]) \). Since \( \sigma_S \) is an isomorphism, \( [\Delta(E)] = [E] \). The part of \( D_\sigma \) corresponding to infinite atoms has trivial \( K_0 \) by Lemma 19.22. So it follows that \( [E] = [\Delta_i(E)] \). This completes the proof. 

19.26 Corollary. Let \( \mathcal{N} \) be a nest on a separable space. Let \( A_i \) denote the set of finite rank atoms of \( \mathcal{N} \). Then \( K_0(\mathcal{T}(\mathcal{N})) \) is isomorphic to

\[ \{g : A_i \to \mathbb{Z} : \sup_{A \in A_i} \frac{|g(A)|}{\dim A} < \infty\} \]

if \( A_i \) is nonempty, and 0 otherwise.

The proof is left as Exercise 19.7. Note that if there are \( n \) finite atoms, then \( K_0(\mathcal{T}(\mathcal{N})) \cong \mathbb{Z}^n \). Also if there are countably many atoms and the dimensions of the atoms are bounded above, then \( K_0(\mathcal{T}(\mathcal{N})) \) is all bounded sequences of integers. In general, the sequence is bounded by \( C\dim A : A \in A_i \) for some constant \( C \).

Notes and Remarks.

Theorem 19.1 and Corollary 19.2 are due to Christensen [2], as is Lemma 19.4 and Theorem 19.7. Theorem 19.10 is due to Wagner [2]. Proposition 19.11 is again due to Christensen. Theorem 19.12 is in Christensen and Peligrad [1]. Theorem 19.14 is a combination of Peligrad [1] and a special case of a theorem of Akemann and Wright [1]. Theorem 19.15 is also due to Peligrad. Lemma 19.16 is due to R. Phillips [1]. Theorems 19.18 and 19.20 are due to Akemann and Johnson [1]. Theorem 19.21 is due to Johansen [1].

We now present a brief outline of cohomology. There is an extensive literature about cohomology of Banach algebras and \( C^* \)-algebras. In particular, see Johnson [2] and Ringrose [7].

Let \( \mathcal{A} \) be a Banach algebra and let \( \mathcal{M} \) be a Banach \( \mathcal{A} \) bimodule. The space \( \mathcal{O}^n(\mathcal{A}, \mathcal{M}) \) of \( n \)-cochains is the space of all bounded \( n \)-linear maps of \( \mathcal{A}^{\otimes n} \) into \( \mathcal{M} \). By convention, \( \mathcal{O}^0(\mathcal{A}, \mathcal{M}) = \mathcal{M} \). A coboundary operator \( \partial_n \) is defined from \( \mathcal{O}^n(\mathcal{A}, \mathcal{M}) \) into \( \mathcal{O}^{n+1}(\mathcal{A}, \mathcal{M}) \) by
\[(\partial_n \phi)(A_0, \ldots, A_n) = A_0 \phi(A_1, \ldots, A_n) + \sum_{j=1}^{n} (-1)^j \phi(A_0, \ldots, A_{j-2}, A_{j-1}A_j, A_{j+1}, \ldots, A_n) + (-1)^{n+1} \phi(A_0, \ldots, A_{n-1})A_n.\]

The \(\partial_n\) map on \(C^0(\mathcal{A}, \mathcal{M})\) is given for \(\mathcal{M}\) in \(\mathcal{M}\) by the inner derivation \(\partial \mathcal{M}(\mathcal{A}) = AM - MA\). By convention, we use \(\partial\) instead of \(\partial_n\) since \(n\) is usually clear in context. A routine but tedious computation shows that \(\partial^2 = 0\). For \(n \geq 1\), the space \(Z^n(\mathcal{A}, \mathcal{M})\) of \(n\)-cocycles is the kernel of \(\partial_n\). The space \(B^n(\mathcal{A}, \mathcal{M})\) of \(n\)-coboundaries is the image of \(\partial_{n-1}\). Since \(\partial^2 = 0\), it follows that \(B^n(\mathcal{A}, \mathcal{M})\) is a subspace of \(Z^n(\mathcal{A}, \mathcal{M})\). The \(n\)th cohomology space of \(\mathcal{A}\) with coefficients in \(\mathcal{M}\) is

\[H^n(\mathcal{A}, \mathcal{M}) = Z^n(\mathcal{A}, \mathcal{M}) / B^n(\mathcal{A}, \mathcal{M}).\]

When \(\mathcal{A}\) is a dual space, one naturally considers dual normal bimodules \(\mathcal{M}\) and restricts attention to bounded multilinear maps which are also weak*-weak* continuous. In this way, one obtains the cohomology spaces \(H^n_\omega(\mathcal{A}, \mathcal{M})\). An algebra \(\mathcal{A}\) is called amenable if \(H^n(\mathcal{A}, \mathcal{M}) = 0\) for every dual normal bimodule \(\mathcal{M}\).

Consider \(n = 1\). If \(\phi\) belongs to \(Z^1(\mathcal{A}, \mathcal{M})\), then \(\phi\) is a linear map of \(\mathcal{A}\) into \(\mathcal{M}\) such that

\[0 = \partial \phi(A, B) = A\phi(B) - \phi(AB) + \phi(A)B.\]

This is precisely the condition that \(\phi\) can be derivation. The coboundaries are precisely the inner derivations. So \(H^1(\mathcal{A}, \mathcal{M}) = 0\) is a reformulation of the statement that every derivation of \(\mathcal{A}\) into \(\mathcal{M}\) is inner.

We now state some of the important results for \(C^*\)-algebras and von Neumann algebras. The first three are taken from Johnson, Kadison and Ringrose [1].

**Theorem.** Let \(\mathcal{A}\) be a \(C^*\)-algebra, and let \(\mathcal{M}\) be an \(\mathcal{A}^n\) dual normal bimodule. Then

\[H^n(\mathcal{A}, \mathcal{M}) = H^n_\omega(\mathcal{A}, \mathcal{M}) = H^n(\mathcal{A}^n, \mathcal{M}) = H^n_\omega(\mathcal{A}^n, \mathcal{M}).\]

**Theorem.** Every AF von Neumann algebra \(\mathcal{A}\) is amenable. (i.e. \(H^n(\mathcal{A}, \mathcal{M}) = 0\) for all \(n \geq 1\) and every dual normal bimodule \(\mathcal{M}\).)

**Corollary.** Every type I von Neumann algebra is amenable.

The celebrated derivation theorem of Kadison [1] and Sakai [2] can be reformulated as:
Theorem. For every von Neumann algebra $\mathcal{A}$, $H^1(\mathcal{A},\mathcal{A}) = 0$. (i.e. Every derivation of $\mathcal{A}$ into itself is inner.)

The main result for nest algebras is due to Lance [2].

Theorem. Let $\mathcal{N}$ be a nest, and let $\mathcal{M}$ be a weak* closed unital subspace of $\mathcal{B}(\mathcal{N})$ which is a $\mathcal{T}(\mathcal{N})$ bimodule. Then $H^n(\mathcal{T}(\mathcal{N}),\mathcal{M}) = 0$ for all $n \geq 1$.

This theorem was used to prove the perturbation result Corollary 18.5. The idea was to prove it first for finite subnests. Then if $\mathcal{N}$ and $\mathcal{M}$ are close nests, a limit procedure produces an invertible linear map of $\mathcal{T}(\mathcal{N})$ onto $\mathcal{T}(\mathcal{M})$ close to the identity map. The trivial cohomology

$$0 = H^1(\mathcal{T}(\mathcal{N}),\mathcal{B}(\mathcal{N})) = H^2(\mathcal{T}(\mathcal{N}),\mathcal{B}(\mathcal{N}))$$

$$= H^2(\mathcal{T}(\mathcal{N}),\mathcal{T}(\mathcal{N})) = H^3(\mathcal{T}(\mathcal{N}),\mathcal{T}(\mathcal{N}))$$

is required to apply two perturbation results of Raeburn and Taylor [1] to modify this map to produce an invertible $S$ near $I$ so that $Ad S$ takes $\mathcal{T}(\mathcal{N})$ onto $\mathcal{T}(\mathcal{M})$.

Exercises.

19.1 Let $\alpha_t, t \geq 0$ be a norm continuous semigroup of automorphisms of a Banach algebra $\mathcal{A}$. For $t > 0$, define elements of $\mathcal{B}(\mathcal{A})$ by $\delta_t = t^{-1}(\alpha_t - I)$ and $\mu_t = t^{-1} \int_0^t \alpha_u du$.

(a) Prove that $\delta_t \mu_s = \mu_t \delta_s$ for $s,t > 0$. Hence deduce that $\delta = \lim_{t \to 0} \delta_t$ exists.

(b) Prove that $\delta$ is a derivation, and $\alpha_t = e^{t \delta}$ for $t \geq 0$.

19.2 (Christensen) A weak* closed algebra $\mathcal{A}$ has the automorphism implementation property $AIP(r,s)$ for $r,s > 0$ if every automorphism $\alpha$ in $\text{Aut} \mathcal{A}$ such that $\|\alpha - id\| \leq r$ is of the form $\alpha = Ad A$ for some $A$ in $\mathcal{A}$ with $\|A-I\| \leq s \|\alpha - id\|$. Show that every derivation of such an algebra is inner.

19.3 An alternate proof of Phillip's lemma: Let $P$ be the projection of $\ell_1^*$ onto $\ell_1$ given by $P\phi = \phi |_{c_0}$. Show that if $\phi_n$ is a sequence in $\ell_1^*$ converging weak* to 0, then $P\phi_n$ converges weakly to 0 in $\ell_1$. Hence deduce that $\lim_{n \to \infty} \|P\phi_n\| = 0$.

19.4 Extend Theorem 19.20 to all type I von Neumann algebras.

19.5 Show that the only compact derivation on $\mathcal{B}(\mathcal{N})$ is zero.
19.6 (a) Let $A_4$ and $A_8$ be the algebras of Exercise 17.5. Show that these algebras have derivations which are not inner. Compute $H^{1}(A, A)$.

(b) Let $A_{\infty}$ be the algebra of Exercise 17.5 (c). Show that $\delta_T$ defines a continuous derivation which is not inner.

19.7 Consider the von Neumann algebra $D = \sum_{k \geq 1} \oplus M_{n_k}$.

(a) Show that if $E$ is an idempotent in $M_{m}(D)$, then $E = \sum_{k \geq 1} \oplus E_k$ where $E_k$ is an idempotent in $M_{m}(M_{n_k}) \simeq M_{m n_k}$. Hence $n_k^{-1}\text{rank} E_k$ is bounded.

(b) Let $F$ be another idempotent in $M_{m}(D)$ such that $\text{rank} F_k = \text{rank} E_k$ for all $k$. Show that $F$ is similar to $E$ in $M_{m}(D)$.

(c) Hence deduce that $S(D)$ is isomorphic to $\{g : \mathbb{N} \rightarrow \mathbb{N}_0 \text{ such that } \sup n_k^{-1}g(k) < \infty\}$.

(d) Compute $K_D(D)$. Hence prove Corollary 19.27.
20. Representation and Dilation Theory

The purpose of this chapter is to analyze the structure of contractive representations of nest algebras. This generalizes the classical dilation theory for contractions of Sz. Nagy-Foias and Ando. For motivation, we develop this briefly first. The key tool is the notion of completely positive maps and the dilation theory due to Arveson. This will be developed in the second part of this chapter. Then we develop the nest algebra theory.

Given an operator $A$ on a Hilbert space $H$, we say that an operator $T$ on a Hilbert space $K$ containing $H$ is a dilation of $A$ provided $A^n = P(H)T^n |H$ for all $n \geq 0$. When $A$ is a contraction, we consider, in particular, unitary dilations of $A$.

20.1 Theorem. Let $A$ be a contraction on a Hilbert space $H$. Then $A$ has a unitary dilation $U$ on a Hilbert space $K$. Moreover, if $U$ is minimal in the sense that $K = \bigvee_{n=-\infty}^\infty U^n H$, then $U$ is unique (up to unitary equivalence fixing $H$).

Proof. For any contraction $T$, let $D_T = (I - T^* T)^{1/2}$. Form $K = \sum_{n=-\infty}^{\infty} \mathcal{H}_n$ where each $\mathcal{H}_n = H$. Define a unitary from $\mathcal{H}_{-1} \oplus \mathcal{H}_0$ to $\mathcal{H}_0 \oplus \mathcal{H}_1$ by $\begin{bmatrix} D_A & A \\ -A^* & D_A \end{bmatrix}$. Extend this to a unitary $U$ on $K$ by setting $U$ to be the shift of $\mathcal{H}_n$ onto $\mathcal{H}_{n+1}$ for $n \neq 0, -1$ given by

$$U \sum_{n \neq -1, 0} \mathcal{H}_n = \sum_{n \neq 0, 1} \mathcal{H}_n$$

It is clear that this is unitary. Moreover, the matrix of $U$ is lower triangular with respect to the decomposition of $K$ with $A$ as its $(0,0)$ entry. Hence the $(0,0)$ entry of $U^n$ is $A^n$. That is,

$$P(H_0)U^n |H_0 = A^n \quad \text{for all} \quad n \geq 0$$

This may not be minimal, but $K_0 = \bigvee_{n=-\infty}^\infty U^n H_0$ is the smallest reducing subspace for $U$ containing $H_0$. The restriction $U_0 = U |K_0$ is a minimal unitary dilation. Suppose that $U_1$ is another minimal unitary dilation on
$K_1$. For $n \geq m$ and $x, y$ in $\mathcal{H}$,
\[(U_0^m x, U_0^m y) = (U_0^{n-m} x, y) = (T_1^{n-m} x, y) = (U_1^{n-m} x, y) = (U_1^n x, U_1^n y)\,.
\]

By taking conjugates, this follows for $n < m$ as well. Hence
\[W(\sum_{n=-N}^{N} U_0^n x_n) = \sum_{n=-N}^{N} U_1^n x_n\]
is isometric from a dense subspace of $K_0$ to a dense subspace of $K_1$, and thus extends to a unitary (also denoted by $W$). Clearly, $W | \mathcal{H} = I$ and $WU_0 = U_1W$ which establishes the desired equivalence.

20.2 Corollary (von Neumann's Inequality). Let $A$ be a contraction on a Hilbert space, and let $p$ be a polynomial. Then
\[
\|p(A)\| \leq \|p\|_\infty = \sup_{|z| \leq 1} |p(z)|.
\]

Thus the contractive representations of the disc algebra are parametrized by $b_1(B(\mathcal{H}))$.

Proof. Let $U$ be a unitary dilation of $A$. Then
\[
\|p(A)\| = \|p(U)p(U) | \mathcal{H} \| \leq \|p(U)\| = \|p\|_\infty.
\]

If $\phi$ is a contractive representation of the disc algebra, then $A = \phi(z)$ is a contraction. The inequality shows that every $A$ in the unit ball of $B(\mathcal{H})$ leads to a contractive representation.

The disc algebra $A(D)$ is a unital subalgebra of $C(T)$, the continuous functions on the unit circle. A $C(T)$ dilation of a representation $\rho$ of $A(D)$ on $\mathcal{H}$ is a $*$ representation $\pi$ of $C(T)$ on $K$ and an isometry $V$ imbedding $\mathcal{H}$ in $K$ such that
\[
\rho(f) = V^* \pi(f) V \text{ for all } f \in A(D).
\]

20.3 Corollary. Every contractive representation $\rho$ of $A(D)$ has a $C(T)$ dilation.

Proof. Let $A = \rho(z)$ and let $U$ be a unitary dilation of $A$ on $K$. Define $\pi(f) = f(U)$ for $f$ in $C(T)$ by the functional calculus. Then the properties of the dilation imply that
\[
\rho(p) = F(\mathcal{H})p(U) | \mathcal{H} = V^* \pi(p) V \text{ for every polynomial } p,
\]
where $V$ is the natural imbedding of $\mathcal{H}$ into $K$. By continuity, $\pi$ is a $C(T)$ dilation of $\rho$. 

Now, consider two commuting contractions, or equivalently, two commuting representations of the disc algebra.

20.4 Ando’s Theorem. Let $A_1$ and $A_2$ be commuting contractions. Then they have commuting unitary dilations on a Hilbert space $K$ such that

$$P(K)V_1^*V_2^* | K = A_1^n A_2^m$$

for all $n, m \geq 0$.

Proof. The main step is to dilate $A_1$ and $A_2$ to commuting isometries. Let $K = \sum_{n \geq 0} \oplus \mathcal{H}_n$ where $\mathcal{H}_0 = K$ and $\mathcal{H}$ is identified with $\mathcal{H}_0$. Let $D_i = D_{A_i}$ and define isometries $V_i$ on $K$ by

$$V_i \sum_{n=0}^{\infty} \oplus h_n = A_i h_0 \oplus D_i h_0 \oplus 0 \oplus \sum_{n \geq 5} \oplus h_{n-2}.$$ 

Note that, although $V_1$ and $V_2$ do not commute,

$$P(\mathcal{H}_0)V_1^*V_2^* | \mathcal{H}_0 = A_1^n A_2^m$$

for all $n, m \geq 0$.

Also

$$V_1V_2 \sum_{n=0}^{\infty} \oplus h_n = A_1 A_2 h_0 \oplus D_1 A_2 h_0 \oplus 0 \oplus D_2 h_0 \oplus 0 \oplus \sum_{n \geq 5} \oplus h_{n-4}$$

and

$$V_2V_1 \sum_{n=0}^{\infty} \oplus h_n = A_1 A_2 h_0 \oplus D_2 A_1 h_0 \oplus 0 \oplus D_1 h_0 \oplus 0 \oplus \sum_{n \geq 5} \oplus h_{n-4}.$$ 

However,

$$\|D_1 A_2 h \|^2 + \|D_2 h \|^2 = \|A_2 h \|^2 - \|A_1 A_2 h \|^2 + \|D_2 h \|^2$$

$$= \|h \|^2 - \|A_1 A_2 h \|^2$$

$$= \|A_1 h \|^2 - \|A_2 A_1 h \|^2 + \|D_1 h \|^2$$

$$= \|D_2 A_1 h \|^2 + \|D_1 h \|^2.$$ 

Hence there is a unitary $W$ of $\mathcal{K}^{(4)}$ onto itself such that

$$W(D_1 A_2 h \oplus 0 \oplus D_2 h \oplus 0) = D_2 A_1 h \oplus 0 \oplus D_1 h \oplus 0$$

for all $h$ in $\mathcal{K}$. Let $\tilde{W}$ act on $K$ by

$$\tilde{W} \sum_{n \geq 0} \oplus h_n = h_0 \oplus \sum_{k \geq 0} W(h_{4k+1} \oplus h_{4k+2} \oplus h_{4k+3} \oplus h_{4k+4}).$$
Then $\tilde{V}_1 = \tilde{W}V_1$ and $\tilde{V}_2 = V_1\tilde{W}^*$ are isometries. Now $V_2\tilde{V}_1 = V_2V_1$ and

\[
\begin{align*}
\tilde{V}_1\tilde{V}_2\sum_{n=0}^{\infty} & \oplus h_1 = \tilde{W}V_1V_2\tilde{W}^* \sum_{n \geq 0} h_n \\
& = \tilde{W}(A_1A_2h_0 \oplus (D_1A_2h_0 \oplus 0 \oplus D_2h_0 \oplus 0) \\
& \quad \quad \oplus \sum_{k \geq 1} W^*(h_{4k-3} \oplus h_{4k-2} \oplus h_{4k-1} \oplus h_{4k})) \\
& = A_1A_2h_0 \oplus (D_1A_2h_0 \oplus 0 \oplus D_2h_0 \oplus 0) \oplus \sum_{n \geq 5} h_{n-4} \\
& = V_2\tilde{V}_1 \sum_{n \geq 0} h_n .
\end{align*}
\]

So $\tilde{V}_1$ and $\tilde{V}_2$ are the desired isometric dilations of $A_1$ and $A_2$. In particular, they have the form $\tilde{V}_i = \begin{bmatrix} A_i & 0 \\ 0 & * \end{bmatrix}$ on $\mathcal{H} \oplus (\mathcal{K} \oplus \mathcal{H})$.

Define $T_1 = \begin{bmatrix} \tilde{V}_1^* & 0 \\ 1 - \tilde{V}_1\tilde{V}_1^* & \tilde{V}_1 \end{bmatrix} = \begin{bmatrix} * & 0 & 0 \\ 0 & A_1 & 0 \\ 0 & * & * \end{bmatrix}$ on $\mathcal{K} \oplus \mathcal{K} \cong K \oplus \mathcal{H} \oplus (K \oplus \mathcal{H})$. This is unitary and dilates $A_1$. Extend $\tilde{V}_2$ to an isometry $T_2$ as follows. Set $T_2\sum_{n=0}^{N} T_1^{-n}k_n = \sum_{n=0}^{N} T_1^{-n}(\tilde{V}_2k_n)$. This is well defined since $\sum_{n=0}^{N} T_1^{-n}k_n = 0$ implies

\[
\sum_{n=0}^{N} T_1^{-n}(\tilde{V}_2k_n) = T_1^{-N}\sum_{n=0}^{N} \tilde{V}_1^{N-n}\tilde{V}_2k_n = T_1^{N}\tilde{V}_2T_1^n \sum_{n=0}^{N} T_1^{-n}k_n = 0 .
\]

Moreover, $\sum_{n=0}^{N} T_1^{-n}k_n = T_1^{-N}\sum_{n=0}^{N} \tilde{V}_1^{N-n}k_n$ has the same norm as $T_1^{-N}\tilde{V}_2\sum_{n=0}^{N} \tilde{V}_1^{N-n}k_n$, and thus $T_2$ is isometric on this set. Extend $T_2$ by continuity to an isometry on $\bigvee_{n \geq 0} T_1^{-n}\mathcal{K} = \mathcal{K} \oplus \mathcal{K}$. Define $T_2|\mathcal{K}^0 \oplus 0$ to be the identity. Then $T_2$ is an isometry on $\mathcal{K} \oplus \mathcal{K}$. Since $\mathcal{K}^0 \oplus 0$ is invariant for $T_1$ and $T_2$, it is clear that they commute.

Now dilate $T_1$ to $U_1 = T_1^{[\omega]}$ on $(\mathcal{K} \oplus \mathcal{K})^{[\omega]}$, and dilate $T_2$ to $U_2$ on $(\mathcal{K} \oplus \mathcal{K})^{[\omega]}$ as in Theorem 20.1:

\[
U_2\sum_{n=-\infty}^{\infty} \oplus x_n = \sum_{n < 0} \oplus x_{n-1} \oplus (D_{T_2}x_{-1} + T_2x_0) \\
\oplus (D_{T_2}x_0 - T_2x_{-1}) \oplus \sum_{n > 1} \oplus x_{n-1} .
\]

By Fuglede’s Theorem, $T_1$ commutes with $T_2^*$; and hence $U_1$ commutes
with $U_2$. By construction, $U_1$ and $U_2$ have the form

$$
\begin{bmatrix}
* & 0 & 0 \\
* & A & 0 \\
* & * & *
\end{bmatrix}
$$

with respect to the decomposition

$$(\sum_{n<0} \oplus (K \oplus K) \oplus K) \oplus \mathcal{H} \oplus (K \oplus \mathcal{H}) \oplus \sum_{n \geq 1} \oplus (K \oplus K)$$

From this, the identity $P(\mathcal{H})U_1^nU_2^m | \mathcal{H} = A_1^nA_2^m$ for $n, m \geq 0$ is immediate.

We remark that the lower triangular form of $U_i$ with respect to some decomposition is a consequence of the theorem even if it is not in evidence in the proof. To see this, note that one obtains a representation $\pi$ of the bidisc algebra $A(D^2)$ by sending a polynomial $p(z_1, z_2)$ to $p(U_1, U_2)$. This is contractive because $U_i$ are commuting unitaries. The compression of this representation to $\mathcal{H}$ is still a representation. Hence $\mathcal{H}$ is semi-invariant for $\pi$ by Theorem 2.16. This argument also yields the generalization of von Neumann’s inequality:

$$\|p(A_1, A_2)\| \leq \|p\|_{\infty}$$

for commuting contractions $A_1, A_2$ and polynomials $p$ in $A(D^2)$. This inequality fails for commuting triples.

20.5 Corollary (Sz.-Nagy-Foias Lifting Theorem). Let $A$ and $X$ be commuting contractions on $\mathcal{H}$, and let $U$ be a unitary dilation of $A$ on $K$. Then $X$ has a dilation $Y$ on $K$ commuting with $U$ such that $\|Y\| = \|X\|$ and

$$P(\mathcal{H})Y^nU^m | \mathcal{H} = X^nA^m \quad \text{for all } n, m \geq 0$$

Proof. Normalize $X$ to have $\|X\| = 1$. Let

$$U_A = \begin{bmatrix}
* & 0 & 0 \\
* & A & 0 \\
* & * & *
\end{bmatrix} \quad \text{and} \quad U_X = \begin{bmatrix}
* & 0 & 0 \\
* & X & 0 \\
* & * & *
\end{bmatrix}$$

be a commuting unitary dilation. The minimal unitary dilation $U_0$ of $A$ is equivalent to the restriction of $U_A$ to $K_0 = (\bigvee_{n<0} U^n_\mathcal{H}) \oplus \mathcal{H} \oplus (\bigvee_{n>0} U^n_\mathcal{H})$, and $U_A \cong U_0 \oplus U_2$. Since $U_X$ commutes with $U_A$, the compression $Y_0$ of $U_X$ to $K_0$ commutes with $U_0$. Moreover, because of the structure of $U_X$ and $K_0$, it follows that $Y_0$ has the form

$$\begin{bmatrix}
* & 0 & 0 \\
* & X & 0 \\
* & * & *
\end{bmatrix}$$

The identity

$$P(\mathcal{H})Y^n_0U^m_0 | \mathcal{H} = X^nA^m \quad \text{for all } n, m \geq 0$$

is now immediate. In general, $U \cong U_0 \oplus U_2$ and the desired dilation can be taken to by $Y \cong Y_0 \oplus 0$. ■

Let $B$ be a C*-algebra. A closed subspace $S$ of $B$ is an operator system if it contains the unit and is adjoint closed. For any closed subspace $A$ of $B$, let $M_n(A)$ denote the subspace of the C*-algebra $M_n(B)$ consisting of all $n \times n$ matrices with coefficients in $A$. If $S$ is an operator system, then $M_n(S)$ also has an order structure from the order in $M_n(B)$. Suppose that $\phi$ is a linear map of $A$ into a C*-algebra $C$. Define $\phi_n$ from $M_n(A)$ into $M_n(C)$ by $\phi_n([A_{ij}]) = [\phi(A_{ij})]$. The map $\phi$ is completely bounded if

$$\|\phi\|_{cb} = \sup_{n \geq 1} \|\phi_n\| < \infty.$$ 

In particular, $\phi$ is completely contractive if $\|\phi\|_{cb} \leq 1$. When $A = S$ is an operator system, say that $\phi$ is completely positive if $\phi_n^{(a)}$ is positive for all $n \geq 1$. The connection between these two notions is quite strong.

20.6 Lemma. Let $\phi$ be a completely positive map on an operator system $S$. Then

$$\|\phi\|_{cb} = \|\phi\| = \|\phi(1)\|.$$ 

Proof. Clearly, $\|\phi(1)\| \leq \|\phi\| \leq \|\phi\|_{cb}$. Let $S = (S_{ij})$ belong to $M_n(S)$ with $\|S\| \leq 1$, and let $X = \phi_n^{(a)}(S)$. Note that the $n \times n$ identity matrix $I_n$ belongs to $M_n(S)$, and $P = \phi_n^{(a)}(I_n) = \phi(1)^{n(a)}$. Since $\begin{bmatrix} I_n & S \\ S^* & I_n \end{bmatrix}$ is positive,

$$O_{2n} \leq \phi_n^{(a)} \begin{bmatrix} I_n & S \\ S^* & I_n \end{bmatrix} = \begin{bmatrix} P & X \\ X^* & P \end{bmatrix}.$$ 

Thus

$$O_n \leq \begin{bmatrix} X^* & -\|X\|I_n \\ -\|X\|I_n & X \end{bmatrix} \begin{bmatrix} P & X \\ X^* & P \end{bmatrix} \begin{bmatrix} X \\ X^*X \end{bmatrix} = X^*PX + \|X\|^2P - 2\|X\|X^*X.$$ 

Hence $2\|X\|^2 \leq 2\|X\|^2\|P\|$, or $\|X\| \leq \|P\| = \|\phi(1)\|$. Thus $\|\phi^{(a)}\| = \|\phi(1)\|$ for all $n \geq 1$. ■

20.7 Lemma. Let $A$ be a unital subspace of a C*-algebra $B$. Let $\phi$ be a unital contraction from $A$ into a C*-algebra $C$. Let $S = A + A^*$, and define $\phi$ on $S$ by

$$\tilde{\phi}(A+B^*) = \phi(A) + \phi(B)^*$$ 

for all $A, B$ in $A$.

Then $\tilde{\phi}$ is a well defined positive map.
Remark. It is easy to see, then, that \( \tilde{\phi} \) is the unique positive extension of \( \phi \) to \( \mathcal{A} + \mathcal{A}^* \).

Proof. To show that \( \tilde{\phi} \) is well defined, it suffices to show that if \( A \) and \( A^* \) belong to \( \mathcal{A} \), then \( \phi(A^*) = \phi(A)^* \). By considering Re \( A \) and Im \( A \), it suffices to consider \( A = A^* \). Let \( \phi(A) = X = U + iV \) where \( U \) and \( V \) are self-adjoint. Now,

\[
\max(\|V + tI\|, \|V - tI\|) = \|V\| + t.
\]

Since \( \|A \pm itI\|^2 = \|A\|^2 + t^2 \),

\[
(\|A\|^2 + t^2)^{1/2} \geq \|\phi(A \pm itI)\| = \|U + i(V \pm tI)\| \geq \|V \pm tI\|.
\]

Thus, \( \|V\| + t \leq (\|A\|^2 + t^2)^{1/2} \) for all \( t \geq 0 \). In the limit as \( t \) increases, one obtains \( \|V\| = 0 \). Hence \( \phi(A) \) is self-adjoint, and \( \phi \) is well defined.

In fact, \( \phi \) is positive on \( \mathcal{A} \cap \mathcal{A}^* \). For if \( A = A^* \) is positive, let \( U = \phi(A) \) and \( \epsilon = \inf\{\lambda : \lambda \in \sigma(U)\} \). For \( t \geq \|A\| \),

\[
t \geq \|A - tI\| \geq \|\phi(A - tI)\| = \|U - tI\| = t - \epsilon.
\]

Thus \( \epsilon \geq 0 \) and \( U \) is positive.

Now let \( S \) be a positive element of \( S \). To show that \( \tilde{\phi}(S) \) is positive, it suffices to show that \( f(\tilde{\phi}(S)) \geq 0 \) for every positive state \( f \) on \( \mathcal{C} \). Clearly, \( F = f \circ \phi \) is a norm one linear functional on \( \mathcal{A} \) with \( F(1) = 1 \). Let \( \tilde{F} \) be any Hahn-Banach extension of \( F \) to all of \( B \). The previous paragraphs applied to \( \tilde{F} \) instead of \( \phi \) shows that \( \tilde{F} \) is a state on \( B \). In particular, it is positive. So for all \( A \) and \( B \) in \( \mathcal{A} \),

\[
\tilde{F}(A + B^*) = F(A) + F(B^*) = f(\phi(A)) + f(\overline{\phi(B)}) = f(\phi(A) + \phi(B)^*) = f(\tilde{\phi}(A + B^*)).
\]

Thus, \( f(\tilde{\phi}(S)) = \tilde{F}(S) \geq 0 \) as desired.

20.8 Corollary. Assume the hypotheses of Lemma 20.7. Then \( \phi \) is completely contractive if and only if \( \phi \) is completely positive.

Proof. If \( \tilde{\phi} \) is completely positive, then \( \tilde{\phi} \) is completely contractive by Lemma 20.6. So \( \phi \) is completely contractive. Conversely, if \( \phi^{(n)} \) is contractive, then since \( \mathcal{M}_n(S) = \mathcal{M}_n(\mathcal{A}) + \mathcal{M}_n(\mathcal{A})^* \), it is easy to see that \( \tilde{\phi}^{(n)} = (\phi^{(n)}) \). Thus \( \tilde{\phi}^{(n)} \) is positive by Lemma 20.7. So \( \tilde{\phi} \) is completely positive.

20.9 Lemma. Let \( S \) be an operator system in a \( C^* \)-algebra \( B \), and suppose that \( \phi \) is a completely positive map of \( S \) into \( \mathcal{M}_n \). Then there is a completely positive map \( \psi \) of \( B \) into \( \mathcal{M}_n \) extending \( \phi \).
**Proof.** Let \( e_1, \ldots, e_n \) be the standard basis for \( \mathcal{C}^n \). Let \( \xi = e_1 \oplus \cdots \oplus e_n \) be a given vector in \( \mathcal{C}^n \oplus \cdots \oplus \mathcal{C}^n \). Define a linear functional \( \Phi \) on \( \mathcal{M}_k(S) \) by
\[
\Phi([S_{ij}]) = (\phi^{(m)}[S_{ij}]) \xi \xi.
\]
This is the composition of two positive maps, and thus is positive. Let \( \Psi \) be any Hahn-Banach extension of \( \Phi \) to \( \mathcal{M}_n(B) \).

It is a well known result of Krein that \( \Psi \) is positive. To see this, note first that \( ||\Phi|| = |\Phi(L_n)| \). For if \( S = S^* \) is self-adjoint, norm one, then
\[
\Phi(-L_n) \leq \Phi(S) \leq \Phi(L_n).
\]
Thus \( |\Phi(S)| \leq |\Phi(L_n)| \). If \( S \) is an arbitrary norm one element, multiply it by a scalar \( \lambda \) of modulus one so that \( \Phi(\lambda S) \geq 0 \). Then since \( \Phi(S^*) = \Phi(S) \), one has
\[
|\Phi(S)| = |\Phi(Re \lambda S)| \leq |\Phi(L_n)|.
\]
Thus \( ||\Psi|| = |\Psi(L_n)| \) as well. By Lemma 20.7 applied to \( \Psi(L_n)^{-1} \Psi \), one sees that \( \Psi \) is positive.

Now define \( \psi \) from \( B \) into \( \mathcal{M}_n \) as follows. Let \( E_{ij} \) be the matrix units for \( \mathcal{M}_n \) with respect to the standard basis. Then \( B \otimes E_{ij} \) represents the \( n \times n \) matrix with \( B \) in the \((i,j)\) entry and \( O_n \)'s elsewhere. Set
\[
\psi(B) = \sum_{i=1}^n \sum_{j=1}^n \psi(B \otimes E_{ij})E_{ij}.
\]
A routine computation shows that for \( S \) in \( S \),
\[
\psi(S) = \sum_{i=1}^n \sum_{j=1}^n \Phi(S \otimes E_{ij})E_{ij} = \sum_{i=1}^n \sum_{j=1}^n \Phi(S)e_j e_i E_{ij} = \phi(S).
\]
So \( \psi \) extends \( \phi \).

We now verify that \( \psi \) is completely positive. Let \([B_{kl}]\) be a positive element of \( \mathcal{M}_m (B) \). Let \( x = x_1 \oplus \cdots \oplus x_m \) belong to \( C^{nm} = \mathcal{C}^n \oplus \cdots \oplus \mathcal{C}^n \), and write \( x_k = \sum_{i=1}^n x_{ki} e_i \). Then
\[
(\psi^{(m)}([B_{kl}])x, x) = \sum_{k,l=1}^m \psi(B_{kl})x_k x_k = \sum_{k,l=1}^m \sum_{i,j=1}^n \psi(B_{kl} \otimes E_{ij})x_{ki} x_{kj} = \psi([C_{ij}])
\]
where \( C_{ij} = \sum_{k,l=1}^m x_{ki} x_{lj} B_{kl} \). To prove that this is positive, it suffices to show that \( C = [C_{ij}] \) is positive. Let \( y = y_1 \oplus \cdots \oplus y_n \) be a vector in
\[ \mathcal{O}^n = \mathcal{O}^n \oplus \cdots \oplus \mathcal{O}^n. \] Then
\[ (Cy_j,y_i) = \sum_{i,j=1}^n (C_{ij} y_j, y_i) = \sum_{i,j=1}^n \sum_{k,l=1}^m (B_{kl} z_{ij} y_j, z_{kl} y_i) \]
\[ = (B_{kl} z, z) \geq 0 \]
where \( z = z_1 \oplus \cdots \oplus z_m \) belongs to \( \mathcal{O}^{nm} \), and \( z_k = \sum_{i=1}^n z_{ki} y_i \). So \( \psi^{(m)} \) is positive for all \( m \geq 1 \), and the lemma follows. \( \blacksquare \)

**20.10 Arveson’s Extension Theorem.** Let \( S \) be an operator system in \( C^*\)-algebra \( B \), and suppose that \( \phi \) is a completely positive map of \( S \) into \( B (\mathcal{H}) \). Then \( \phi \) has a completely positive extension \( \psi \) of \( B \) into \( B (\mathcal{H}) \).

**Proof.** Fix an increasing sequence \( P_n \) of projections of rank \( n \) with \( \sup P_n = I \). Define \( \phi_n (B) = P_n \phi (B) P_n \mathcal{H} \). This is a completely positive map of \( S \) into \( B (P_n \mathcal{H}) \) which is \( * \)-isomorphic to \( \mathcal{M}_n \). So by Lemma 20.9, \( \phi_n \) has a completely positive extension \( \psi_n \) of \( B \) into \( B (P_n \mathcal{H}) \). Since \( \| \psi_n \|_{cp} = \| \phi_n (1) \| = \| P_n \phi (1) P_n \| \leq \| \phi (1) \| \), this is a bounded sequence of c.b. maps. It remains to take a limit point in some appropriate topology.

The topology we use is the pointwise weak* topology (\( PW^* \)) on linear maps of \( B \) into \( B (\mathcal{H}) \) given by pointwise weak* convergence. That is, \( \Phi_\alpha \) converges \( PW^* \) to \( \Phi \) if
\[ w^* \text{-} \lim \Phi_\alpha (B) = \Phi (B) \quad \text{for all} \quad B \in B. \]
As in the proof of the Banach-Alaoglu theorem, the map taking the unit ball of \( B (B, B (\mathcal{H})) \) into \( \prod_{B \in B} \| B \| (B (\mathcal{H}), w^*) \) is a homeomorphism from the \( PW^* \) topology to a closed subset of a compact Hausdorff space. Hence the unit ball is \( PW^* \) compact.

It will be shown that the set of completely positive maps is \( PW^* \) closed. To this end, suppose that \( \Phi_\alpha \) are completely positive and \( \Phi \) is the \( PW^* \)-limit of \( \Phi_\alpha \). Let \( \{ B_{ij} \} \) be a positive element of \( \mathcal{M}_n (B) \). Then
\[ \phi^{(n)} ([B_{ij}]) = w^* \text{-} \lim \Phi_\alpha^{(n)} ([B_{ij}]) \geq 0 \]
since the positive operators are weak* closed. Hence the c.p. maps of norm at most \( \| \phi (1) \| \) forms a compact set in the \( PW^* \) topology.

Let \( \psi \) be any \( PW^* \) cluster point of the sequence \( \psi_n \). Then \( \psi \) is completely positive. Since \( \phi \) is the \( PW^* \) limit of \( \phi_n \), it follows that \( \psi \) is an extension of \( \phi \) as desired. \( \blacksquare \)

**20.11 Corollary.** Let \( A \) be a unital subspace of a \( C^*\)-algebra \( B \), and let \( \phi \) be a unital complete contraction of \( A \) into \( B (\mathcal{H}) \). Then there exists a completely positive map \( \psi \) of \( B \) into \( B (\mathcal{H}) \) extending \( \phi \).
Proof. By Corollary 20.8, \( \phi \) extends to a completely positive map \( \bar{\phi} \) of \( \mathcal{A} + \mathcal{A}^* \) into \( B(\mathcal{H}) \). Apply Theorem 20.10 to \( \bar{\phi} \).

The next step is a basic structure theorem for unital completely positive maps. This theorem shows that completely positive maps dilate to representations. Equivalently, it says that all c.p. maps are corners of representations.

20.12 Stinespring’s Dilation Theorem. Let \( B \) be a \( C^* \)-algebra, and let \( \phi \) be a unital completely positive map of \( B \) into \( B(\mathcal{H}) \). Then there exists a unital \( * \) representation \( \pi \) of \( B \) on a Hilbert space \( K \) and an isometry \( V \) of \( \mathcal{H} \) into \( K \) such that

\[
\phi(B) = V^* \pi(B)V \quad \text{for all } B \text{ in } B.
\]

Proof. Consider the algebraic tensor product \( B \otimes \mathcal{H} \), and define a sesquilinear form by

\[
\langle A \otimes x, B \otimes y \rangle = (\phi(B^*A)x,y)
\]

and extend by linearity. This is positive semidefinite since

\[
\sum_{i=1}^{n} A_i \otimes x_i, \sum_{i=1}^{n} A_i \otimes x_i = \sum_{i=1}^{n} \sum_{j=1}^{n} (\phi(A_i^*A_j)x_j,x_i)
\]

\[
= (\phi^{(n)}(A_i^*A_j)x,x) \geq 0
\]

where \( x = x_1 \oplus \ldots \oplus x_n \). Thus this satisfies the Cauchy-Schwartz inequality. So

\[
\mathcal{H} = \{ u \in B \otimes \mathcal{H} : \langle u, u \rangle = 0 \}
\]

\[
= \{ u \in B \otimes \mathcal{H} : \langle u, v \rangle = 0 \text{ for all } v \}
\]

is a subspace. The induced form on \( B \otimes \mathcal{H} / \mathcal{H} \) is thus positive definite. Let \( K \) be the Hilbert space completion of this quotient.

For \( A \) in \( B \), define a linear map \( \pi_0(A) \) on \( B \otimes \mathcal{H} \) by

\[
\pi_0(A)B \otimes x = AB \otimes x
\]

and extending linearly. This is an algebra homomorphism such that

\[
\langle u, \pi_0(A)u \rangle = \langle \pi_0(A^*)u, u \rangle.
\]

Hence for each \( u \) in \( B \otimes \mathcal{H} \), \( \rho_u(A) = \langle \pi_0(A)u, u \rangle \) is a positive linear functional. Hence

\[
\langle \pi_0(A)u, \pi_0(A)u \rangle = \rho_u(A^*A) \leq \| A^*A \| \rho_u(1)
\]

\[
= \| A \|^2 \langle u, u \rangle.
\]

So \( \pi_0(B) \) leaves \( \mathcal{H} \) invariant, and the induced map
\[ \pi(A)(u + \mathcal{N}) = \pi_0(A)u + \mathcal{N} \]
defines a contractive *-representation on the quotient. Hence it extends by continuity to a *-homomorphism into \( B \) (\( K \)).

Next, define \( V \) from \( \mathcal{N} \) into \( K \) by \( Vx = I \otimes x + \mathcal{N} \). Then
\[ \| Vx \|^2 = (\phi(I)x,x) = \| x \|^2, \]
so \( V \) is an isometry. Finally, for \( A \) in \( B \) and \( x, y \) in \( \mathcal{N} \),
\[ (V^*\pi(A)Vx,y) = \langle \pi(A)I \otimes x,I \otimes y \rangle \]
\[ = \langle A \otimes x,I \otimes y \rangle = (\phi(A)x,y) \, . \]
Thus, \( \phi(A) = V^*\pi(A)V \) as required. \( \blacksquare \)

Let \( \mathcal{A} \) be a unital subalgebra of a \( C^* \)-algebra \( B \), and let \( \phi \) be a unital homomorphism of \( \mathcal{A} \) into \( B \) (\( \mathcal{N} \)). Say that \( \phi \) has a \( B \)-dilation if there is a *-homomorphism \( \pi \) of \( B \) on a Hilbert space \( K \) and an isometry \( V \) of \( \mathcal{N} \) into \( K \) such that \( \phi(A) = V^*\pi(A)V \) for all \( A \) in \( \mathcal{A} \). Clearly, \( \phi \) is contractive.

20.13 Corollary (Arveson's Dilation Theorem). Let \( \mathcal{A} \) be a unital subalgebra of a \( C^* \)-algebra \( B \). Let \( \phi \) be a unital contractive representation of \( \mathcal{A} \) into \( B \) (\( \mathcal{N} \)), and let \( \tilde{\phi} \) be the positive extension of \( \phi \) to \( \mathcal{A} + \mathcal{A}^* \). The following are equivalent.
(i) \( \phi \) has a \( B \)-dilation.
(ii) \( \phi \) is completely contractive.
(iii) \( \tilde{\phi} \) is completely positive.

Proof. (ii) and (iii) are equivalent by Corollary 20.8. By Theorem 20.10, \( \phi \) has a completely positive extension to all of \( B \). Hence by Stinespring's Theorem 20.12, \( \phi \) has a \( B \)-dilation. The converse is immediate since *-representations are contractive, whence \( \phi^{(n)} = V^{(n)}\pi^{(n)}V^{(n)} \) is contractive for all \( n \geq 1 \). \( \blacksquare \)

By a finite dimensional nest algebra, we shall mean a nest subalgebra of some $\mathcal{M}_n$. The contractive representations of these algebras are simple and explicit; and are the key to the general analysis.

20.14 Theorem. Let $\mathcal{A}$ be a finite dimensional nest algebra in $\mathcal{M}_n$. Let $E_{ij}$ be the matrix units of $\mathcal{M}_n$ relative to a basis that puts $\mathcal{A}$ in block upper triangular form. Let $\rho$ be a representation of $\mathcal{A}$ on $\mathcal{H}$ such that $\|\rho(E_{ij})\| \leq 1$ for every matrix unit in $\mathcal{A}$. Then $\rho$ has an $\mathcal{M}_n$ dilation. (i.e. There is a $*$ representation $\pi$ on a space $\mathcal{K}$ containing $\mathcal{H}$ such that $\rho(A) = P(\mathcal{K})\pi(A) | \mathcal{K}$ for all $A$ in $\mathcal{A}$.)

Remark. This shows that if $\|\rho(E_{ij})\| \leq 1$ just for the matrix units alone, then $\rho$ is completely contractive.

Proof. First, assume that $\mathcal{A} = T_n$ is the upper triangular algebra in $\mathcal{M}_n$. The operators $P_i = \rho(E_{ii})$ are norm one idempotents which annihilate each other. Thus they are pairwise orthogonal projections. So $\rho(1) = \sum_{i=1}^n P_i$ is an orthogonal projection. Since $\rho(A) = \rho(1)\rho(A)\rho(1)$, we may as well assume that $\rho(1) = I$. The ranges of $P_i$ decompose $\mathcal{H}$ as $\mathcal{H}_1 \oplus \mathcal{H}_2 \oplus \ldots \oplus \mathcal{H}_n$. Now

$$\rho(E_{ij}) = \rho(E_{ii}E_{ij}E_{jj}) = P_i \rho(E_{ij}) P_j.$$ 

Let $T_i = P_i \rho(E_{ii}) | \mathcal{H}_{i+1}$. Then

$$P_i \rho(E_{ij}) | \mathcal{H}_j = P_i \rho(E_{ii}E_{ij}E_{jj}E_{jj} \ldots E_{jj}) | \mathcal{H}_i = T_i T_{i+1} \ldots T_{j-1}.$$ 

Thus $\rho$ is determined by $\mathcal{H} = \mathcal{H}_1 \oplus \ldots \oplus \mathcal{H}_n$ and $\{T_1, \ldots, T_n\}$; and any set of contractions $T_1, \ldots, T_n$ yields a representation $\rho$ with $\|\rho(E_{ij})\| \leq 1$ for all $i \leq j$.

Let us identify $\mathcal{H}_1, \ldots, \mathcal{H}_n$ with a fixed Hilbert space $\mathcal{R}$. If any $\mathcal{H}_i$ are finite dimensional, we can dilate $\rho$ to the representation $\rho \oplus \delta$ where $\delta(E_{ij}) = E_{ij}^{(d)}$ is infinitely many copies of the identity representation. Now each $T_i$ is a contraction in $B(\mathcal{R})$. By Theorem 20.1, each $T_i$ dilates to a unitary $U_i$ on $\mathcal{K}_0 = \bigoplus_{n=\infty}^0 \mathcal{R}_n$ with $\mathcal{R}_0 \cong \mathcal{R}$ so that each $U_i$ is lower triangular and the $(0,0)$ entry is $T_i$. Identify $\mathcal{K}_0$ with $\mathcal{R}$. Note that

$$T_{ij} = T_i T_{i+1} \ldots T_{j-1} = P(\mathcal{R}) U_i U_{i+1} \ldots U_{j-1} | \mathcal{R}.$$ 

Now define a unitary operator

$$W = I \oplus U_1 \oplus U_1 U_2 \oplus \ldots \oplus U_1 \ldots U_{n-1}$$

on $\mathcal{K} = \mathcal{K}_0^{[n]}$. Let $\pi$ be the $*$ representation of $\mathcal{M}_n$ on $\mathcal{K}$ given by infinite inflation conjugated by $W$: 
\[
\pi([a_{ij}]) = W^*[a_{ij}]W = [a_{ij}U_{ij}]
\]
where \( U_{ij} = U_iU_{i+1}...U_{j-1} \) if \( i < j \), \( U_{ii} = 1 \), and \( U_{ji} = U_{ij}^\ast \) for \( i < j \). Now \( \mathcal{H} = \mathcal{R}^{(n)} \), so from the formula of the previous paragraph,
\[
\rho(A) = P(\mathcal{H})\pi(A) |\mathcal{H}
\]
as desired.

Now consider a general finite dimensional nest algebra \( \mathcal{A} \). It contains a copy of \( \mathcal{T}_n \). Restrict \( \rho \) to \( \mathcal{T}_n \) and dilate as above. Then \( \tilde{\rho}(A) = P(\mathcal{H})\pi(A) |\mathcal{H} \) is a completely positive extension of \( \rho |\mathcal{T}_n \) to all of \( \mathcal{M}_n \). But since \( \mathcal{T}_n + \mathcal{T}_n^\ast = \mathcal{M}_n \), it is clear that the positive extension of \( \rho \) to \( \mathcal{M}_n \) is unique. Now consider any matrix unit \( E_{ij} \) in \( \mathcal{A} \) with \( i > j \). Then the identities \( \rho(E_{ij})\rho(E_{ji}) = \rho(E_{ii}) \) and \( \rho(E_{ji})\rho(E_{ij}) = \rho(E_{ii}) \) together with the fact that these operators are contractions yields that \( \rho(E_{ij}) \) and \( \rho(E_{ji}) \) are partial isometries with
\[
\rho(E_{ij})^* = \tilde{\rho}(E_{ji})^* = \tilde{\rho}(E_{ij}).
\]
The matrix units span \( \mathcal{A} \), whence \( \tilde{\rho} |\mathcal{A} = \rho \); and \( \pi \) dilates \( \rho \) as desired. 

**20.15 Corollary.** Every homomorphism \( \rho \) of a finite dimensional nest algebra \( \mathcal{A} \) onto \( \mathfrak{B} (\mathcal{H}) \) is similar to a completely contractive representation, and hence is completely bounded.

**Proof.** By Corollary 17.2 and Exercise 17.1, the restriction of \( \rho \) to \( \mathcal{A} \cap \mathcal{A}^\ast \) is similar to a * representation. So replace \( \rho \) by \( \rho_0 = Ad S_0 \circ \rho \) which is contractive on \( \mathcal{A} \cap \mathcal{A}^\ast \). Let \( F_1, ..., F_k \) be the projections onto the atoms of \( \mathcal{A} \) with \( F_i \leq F_{i+1} \). Let
\[
S_i = \sum_{j=1}^k t^{j-1} \rho(F_j) + \rho(I)^{j-1},
\]
and let \( \rho_t = Ad S_i \circ \rho_0 \) for \( t > 0 \). Then \( \rho_t(E_{ii} + 1) = t \rho_0(E_{ii} + 1) \) if \( E_{ii} + 1 = F_j E_{ii} F_{j+1} \) and \( \| \rho_t(E_{ii} + 1) \| = 1 \) if \( E_{ii} + 1 = F_j E_{ii} F_{j+1} \). So for sufficiently small \( t \), \( \| \rho_t(E_{ij}) \| \leq 1 \) for all matrix units in \( \mathcal{A} \). Thus \( \rho_t \) is a completely contractive representation by Theorem 20.14. It is routine to verify that \( (Ad S)^{(n)} = Ad S^{(n)} \) is bounded by \( \| S \| \| S^{-1} \| \). Hence \( \rho = Ad (S_0 S_0^{-1}) \circ \rho_0 \) is completely bounded, and
\[
\| \rho \|_{cb} \leq \| S_0 S_0^{-1} \| (S_0 S_0^{-1})^{-1} \| .
\]

The next step is to show that general nest algebras can be approximated by subalgebras isomorphic to finite dimensional nest algebras in such a way that the identity operator *approximately factors* through these algebras. By analogy to the corresponding property for von Neumann algebras, this property will be called *semidiscreteness*. The precise definition is the conclusion of the following theorem.
20.16 Theorem. Every nest algebra $\mathcal{T}(\mathcal{N})$ is semidiscrete: There exist finite dimensional nest algebras $A_n$, weak* continuous completely contractive maps $\phi_n: \mathcal{T}(\mathcal{N}) \to A_n$, and weak* continuous completely isometric homomorphisms $\psi_n: A_n \to \mathcal{T}(\mathcal{N})$ such that $\psi_n \circ \phi_n(A)$ converges weak* to $A$ for all $A$ in $\mathcal{T}(\mathcal{N})$.

Moreover, it can be arranged that $K = \lim_{n \to \infty} \psi_n(\phi_n(K))$ in norm for every compact operator in $\mathcal{T}(\mathcal{N})$.

Proof. Let $\mathcal{N}$ be order isomorphic to a subset $\omega$ of $[0,1]$, and let $\mu$ be a Borel measure on $[0,1]$ mutually absolutely continuous to the spectral measure $E_{xy}$ of $\mathcal{N}$. By the results of Chapter 7 (Theorem 7.14 and Corollary 7.16), $\mathcal{N}$ is unitarily equivalent to the canonical nest on

$$\mathcal{N} = L^2(\mu_1) \oplus L^2(\mu_2) \oplus ...$$

where $\mu_k = \chi_{J_k} \mu$ and $J_k$ is a decreasing sequence of Borel subsets of $\omega$.

Fix an integer $N$. Construct a partition of $[0,1]$ into disjoint intervals $I_1, \ldots, I_p$ (in that order) and integer $k_i$ in $[1,N]$ for $1 \leq i \leq p$ such that

i) $\mu(I_i) < N^{-1}$ or $I_i$ is a singleton,

ii) $\mu_k(I_i) > (1-N^{-i})\mu(I_i)$ for $1 \leq i \leq p$, and

iii) $\mu(\bigcup \{I_i: k_i \geq k\}) > (1-N^{-i})\mu_k$.

This is possible since each $\mu_k$ is regular, and hence one can find finitely many disjoint intervals such that i) holds, $\mu_N(I_1) > (1-N^{-i})\mu(I_1)$, and

$$\mu(\bigcup I_i \cap J_N) > (1-N^{-i})\mu(J_N).$$

These intervals will have $k_i = N$. Now expand the set of intervals so that ii) and iii) hold for $N-1$. Proceed in this way until the entire partition is defined.

For $1 \leq i \leq p$ and $1 \leq k \leq k_i$, let $e_i^k$ be the positive multiple of $\chi_{I_i \cap J_k}$ of norm one in $L^2(\mu_k)$. For convenience of notation, set $e_i^k = 0$ if $k < k_i < N$. Let $K_N = \text{span} \{e_i^k: 1 \leq i \leq p, 1 \leq k \leq N\}$. Let $\mathcal{A}_N$ be the finite dimensional nest algebra acting on $K_N$ given by atoms $A_i = \text{span} \{e_i^k: 1 \leq k \leq k_i\}$ with the order $A_1 \ll A_2 \ll \ldots \ll A_p$. It is clear that the map $\phi_N(T) = P(K_N)TP|K_N$ maps $\mathcal{T}(\mathcal{N})$ into $\mathcal{A}_N$. Since this is just a compression map, it is completely contractive. We may also assume that the $(N+1)$st partition is a refinement of the $N$th partition. Unfortunately, this does not imply that the subspaces $K_N$ are nested; but this is not crucial.

Now we construct $\psi_N$. Note that $\mathcal{A}_N$ is spanned by the matrix units $E_{ij}^k = e_i^k \otimes e_j^k$, $1 \leq k, \ell \leq N$, $1 \leq i \leq j \leq p$. Define $\psi_N(E_{ij}^k) = E_{ij}^k$ for $i < j$. For $i = j$ and $1 \leq k, \ell \leq k_i$, let $U_{ij}^{k\ell}$ be the canonical partial isometry from $L^2(I_i \cap J_k) \subseteq L^2(\mu_k)$ to $L^2(I_i \cap J_k) \subseteq L^2(\mu_k)$. Set

$$U_{ij}^{k\ell} = I_{ij}^k \otimes I_{ij}^\ell,$$
\(\psi_N(E_{ji}^{t}) = U_{ji}^{t}\). Extend \(\psi_N\) to all of \(A_N\) by linearity. Note that \(U_{ji}^{t} e_i^t = e_i^t\), and that \(\{E_{ji}^{t} : 1 \leq k, \ell \leq k_i\}\) form matrix units for an algebra * isomorphic to \(B(A_k)\). Moreover, \(E_{ji}^{t} = U_{ji}^{t} E_{ji}^{t} U_{ji}^{t}\) for all \(i < j\), \(1 \leq k, s, t, \ell \leq N\). It is now apparent that \(\psi_N\) is a representation of \(A_N\) which takes the matrix units to contractions. By Theorem 20.17, \(\psi_N\) is completely contractive.

It is clear from the construction that \(\phi_N \circ \psi_N\) is the identity on \(A_N\).

Let us examine \(\psi_N \circ \phi_N\). Properties i), ii) and iii) guarantee that \(\text{dist}(x, \text{span}\{e_i^t : 1 \leq i \leq p\})\) tends to 0 for all \(x \in L^2(\mu)\) as \(N\) tends to infinity. Thus \(\text{dist}(x, K_N)\) tends to 0 as \(N\) tends to infinity for all \(x \in K\). Hence \(P(K_N)\) converges strongly to \(I\). Thus for any \(T\) in \(T(\mathcal{H})\), the sequence \(P(K_N)TP(K_N)\) converges weak* to \(T\). The point is that

\[\psi_N \circ \phi_N(T) - P(K_N)TP(K_N) = P(K_N)^\perp \psi_N \circ \phi_N(T)P(K_N)^\perp\]

because the only error occurs because \(E_{ji}^{t} \neq U_{ji}^{t}\), and

\[U_{ji}^{t} - E_{ji}^{t} = P(K_{N})^{-1}(U_{ji}^{t} - E_{ji}^{t})P(K_{N})^{-1}\].

Since this difference is uniformly bounded by \(\|T\|\), it tends to 0 in the weak* topology. Thus,

\[w^*-\lim_{N \to \infty} \psi_N(\phi_N(T)) = T\]

for every \(T\) in \(T(\mathcal{H})\).

Now consider finite rank operators. Let \(P_s\) be the orthogonal projection onto \(L^2(\mu_1) \oplus \cdots \oplus L^2(\mu_s)\). Let \(R = x \otimes y^*\) be a norm one, rank one operator in \(T(\mathcal{H})\) with \(R = P_s RP_s\) and fix \(\epsilon > 0\). By Lemma 3.7, there is an element \(z = P(N)z\) such that \(x = P(N)z\) and \(y = P(N)\). If \(A = N \otimes N_\perp\) is a proper atom, choose an integer \(N_0 \geq s\) so that \(A\) corresponds to a singleton in the partition of \([0,1]\) for \(A_N, N \geq N_0\). Otherwise, choose \(N_0 \geq s\) sufficiently large that the partition \(I_1, \ldots, I_p\) is sufficiently fine that there is an \(r\) with \(\|E_{\mathcal{H}}(\bigcup_{i=1}^r I_i)^{\perp} x\| < \epsilon\) and

\[\|E_{\mathcal{H}}(\bigcup_{i=1}^r I_i)y\| < \epsilon\]. In either case, one uses the fact that step functions are dense in \(L^2(\mu)\) to choose \(N_1 \geq N_0\) so that \(\|P(K_N)^{\perp} x\| < \epsilon\) and \(\|P(K_N)^{\perp} y\| < \epsilon\) for \(N \geq N_1\). Now for \(N \geq N_1\), one can find an integer \(m\), and constants \(a_i^t\) and \(b_i^t\) so that

\[\|x - \sum_{i=1}^m \sum_{k=1}^s a_i^t e_i^t\| < 2\epsilon\] and \(\|y - \sum_{i=m+1}^p \sum_{k=1}^s b_i^t e_i^t\| < 2\epsilon\)

where \(m' = m + 1\) unless \(I_m\) is a singleton in which case \(m' = m\). Then let \(x_N\) and \(y_N\) be the above approximates in \(K_N\). Note that \(x_N \otimes y_N^*\) belongs to \(A_N\) and \(\psi_N(x_N \otimes y_N^*) = x_N \otimes y_N^*\). Indeed, this is immediate except for the terms \(a_i^t b_i^t E_{ji}^{t}\). But since \(I_m\) is a singleton, \(\psi_N(E_{mm}^{k}) = E_{mm}^{k}\), and all is well. Moreover,
\[ \| x \otimes y^* - x_N \otimes y_N^* \| \leq \| x - x_N \| \| y \| + \| y_N \| \| x - x_N \| < 5\epsilon. \]

Consequently, \( R \) is the limit of (rank one) operators \( R_N \) in the range of \( \psi_N \). Thus
\[ \| R - \psi_n(\phi_n(R)) \| \leq \| R - R_n \| + \| \psi_n \circ \phi_n(R_n - R) \| \]
\[ \leq 2\| R - R_n \|. \]

Hence \( \psi_n \circ \phi_n(R) \) converges to \( R \) in norm.

Clearly, every rank one operator in \( T(\mathcal{N}) \) can be approximated by those of the form \( P_s R P_s \) for some \( s \). So by Corollary 3.13, \( \psi_n \circ \phi_n(K) \) converges in norm to \( K \) for every compact operator in \( T(\mathcal{N}) \).

We are now ready to apply Arveson's dilation theory.

20.17 Corollary. Every weak* continuous, contractive representation of a nest algebra is completely contractive.

Proof. Let \( \rho \) be a weak* continuous contractive representation of \( T(\mathcal{N}) \), and let \( \phi_k \) and \( \psi_k \) be given by Theorem 20.16. Then \( \rho \circ \psi_k \) are contractive representations of \( A_k \), and thus are completely contractive by Theorem 20.14. Hence \( \rho \circ \psi_k \circ \phi_k \) are completely contractive. But \( \rho \) is weak* continuous and \( \psi_k \circ \phi_k \) converges to the identity in the pointwise weak* (FW*) topology. So \( \rho \circ \psi_k \circ \phi_k \) converge to \( \rho \) in the FW* topology, and thus \( \rho \) is completely positive.

20.18 Theorem. Let \( \mathcal{N} \) be a nest on a Hilbert space \( \mathcal{H} \). Let \( \rho \) be a weak* continuous contractive representation of \( T(\mathcal{N}) \) on a Hilbert space \( \mathcal{H} \). Then there is an isometry \( V \) of \( \mathcal{H} \) into \( \mathcal{H}^{[\omega]} \) such that
\[ \rho(A) = V^* A^{[\omega]} V \text{ for all } A \text{ in } T(\mathcal{N}). \]

The range \( V\mathcal{H} \) is a semi-invariant subspace of \( T(\mathcal{N})^{[\omega]} \).

Proof. Let \( K_1 \) denote the unital \( C^* \)-algebra \( \mathcal{K}+\mathbb{C}I \), and let \( \mathcal{A} = T(\mathcal{N}) \cap K_1 \). By Corollary 20.17, \( \rho \) is completely contractive. By Corollary 20.13, \( \rho \mid \mathcal{A} \) has a \( K_1 \) dilation. Namely, there is a representation \( \pi \) of \( K_1 \) on a Hilbert space \( \mathcal{H}' \) and an isometry \( V \) mapping \( \mathcal{H} \) into \( \mathcal{H}' \) such that
\[ \rho(K) = V^* \pi(K) V \text{ for all } K \text{ in } K_1. \]

The representation decomposes as \( \pi = \pi_a \oplus \pi_s \) on \( K_a \oplus K_s \) where \( \pi_a \) is faithful on \( K \) and \( \pi_s \) annihilates \( K \). The range \( V\mathcal{H} \) is contained in \( K_s \). To see this, let \( E_k \) be a sequence of finite rank projections that \( \pi_a \) to the identity. Since \( \rho \) is weak* continuous,
\[ h = \lim_{k \to \infty} \rho(E_k)h = \lim_{k \to \infty} V^*\pi(E_k)Vh = V^*P(K_\delta)Vh \text{ for all } h \in \mathcal{H}. \]

Thus, \( \pi \) can be replaced by \( \pi_\delta \). The only representations of \( K \) are the ampliations \( \pi_n(K) = K^{(n)} \), and there is no loss of generality in assuming that \( n = \infty \). Thus \( \rho(K) = V^*K^{(\infty)}V \) for \( K \) in \( \mathcal{A} \). Since both sides of this identity are weak* continuous, and \( \mathcal{A} \) is weak* dense in \( \mathcal{T}(\mathcal{H}) \) by Theorem 3.11, the identity extends to all \( A \) in \( \mathcal{T}(\mathcal{H}) \).

Since \( \rho \) is a homomorphism, Theorem 2.16 shows that the range \( VH \) is semi-invariant for \( \pi(T(\mathcal{H})) \).

20.19 Proposition. Let \( \mathcal{H} \) be a nest on a Hilbert space \( R \), and let \( \rho \) be a weak* continuous contractive representation of \( \mathcal{T}(\mathcal{H}) \) on \( \mathcal{H} \). Then \( \rho \) has a minimal \( B(R) \) dilation \( \pi \), and \( \pi \) is unique up to a unitary equivalence which fixes \( \mathcal{H} \).

Proof. Consider the dilation of Theorem 20.18. Identify \( \mathcal{H} \) with \( VH \) and let \( K \) be the smallest reducing subspace for \( B(R) \) obtained by restriction to \( K \). Clearly, this is a minimal dilation of \( \rho \). If \( \pi_1 \) is another minimal dilation of \( \rho \) on a space \( K_1 \), define a map \( W \) from \( K \) to \( K_1 \) as follows. Let \( \tilde{\rho} \) be the unique completely positive, weak* continuous extension of \( \rho \) to \( B(R) \) (given by \( \tilde{\rho}(T_1 + T_2^*) = \rho(T_1) + \rho(T_2)^* \) and extending by continuity). For operators \( T_1, \ldots, T_n \) in \( B(R) \) and vectors \( h_1, \ldots, h_n \) in \( \mathcal{H} \),

\[
\| \sum_{j=1}^{n} \pi(T_j)h_j \|^2 = \sum_{j=1}^{n} \sum_{k=1}^{n} \langle \pi(T_j^*T_k)h_j, h_k \rangle \\
= \sum_{j=1}^{n} \sum_{k=1}^{n} \langle \tilde{\rho}(T_j^*T_k)h_j, h_k \rangle \\
= \sum_{j=1}^{n} \sum_{k=1}^{n} \langle \pi_1(T_j^*T_k)h_j, h_k \rangle = \| \sum_{j=1}^{n} \pi_1(T_j)h_j \|^2 .
\]

Thus there is an isometry \( W \) from \( K = \text{span} \{ \pi(T)h : T \in B(R), h \in \mathcal{H} \}^- \) onto \( K_1 = \text{span} \{ \pi_1(T)h : T \in B(R), h \in \mathcal{H} \}^- \) such that

\[ W\pi(T)h = \pi_1(T)h \text{ for all } T \in B(R), h \in \mathcal{H}. \]

Thus \( W \) is unitary, \( Wh = h \) for all \( h \) in \( \mathcal{H} \), and

\[ W\pi(T)\pi(S)h = \pi_1(TS)h = \pi_1(T)\pi_1(S)h = \pi_1(T)W\pi(S)h . \]

Thus \( \pi_1(T) = W\pi(T)W^* \).

In this section, we develop analogues of Ando’s Theorem and the Sz-Nagy-Foias Lifting Theorem for representations of nest algebras.

20.20 Theorem. Let $\mathcal{A}$ be a finite dimensional nest algebra in $\mathcal{M}_n$. Suppose that $\rho$ is a unital contractive representation of $\mathcal{A}$ on $\mathcal{H}$ commuting with a contraction $X$. Then there is an $\mathcal{M}_n$ dilation $\pi$ of $\rho$, and a commuting unitary dilation $U$ of $X$ on a space $K$ such that

$$P(\mathcal{H})U_n^*\pi(A)|\mathcal{H} = X^nA$$ for all $n \geq 0$, $A \in \mathcal{A}$. 

Proof. First take $\mathcal{A} = \mathcal{T}_n$, the upper triangular algebra. Consider the explicit dilation of $\rho$ constructed in Theorem 20.14. First $P_i = \rho(E_{ii})$ are pairwise orthogonal projections. We can assume that these are all the same rank, for otherwise replace $\rho$ by $\rho \oplus \delta$ and $X$ by $X \oplus 0$ where $\delta$ is infinitely many copies of the identity representation. Any dilation of this new pair yields a dilation of $(\rho, X)$. So $\mathcal{H}$ decomposes as $\mathcal{H} = \mathcal{H}_1 \oplus \cdots \oplus \mathcal{H}_n$ where each $\mathcal{H}_i \cong \mathcal{R}$, a fixed space. Since $X$ commutes with $\rho$, $X = X_1 \oplus \cdots \oplus X_n$. As before, let $T_i = P_i\rho(E_{i,i+1})|\mathcal{H}_{i+1}$. Then $X_iT_i = T_iX_{i+1}$ for $1 \leq i \leq n-1$. By Theorem 20.1, each $T_i$ has a unitary dilation $U_i$ on $\mathcal{K}_0 = \bigoplus_{n=-\infty}^{\infty} \mathcal{R}_n$ where $\mathcal{R}_n \cong \mathcal{R}$, $\mathcal{H}_i$ is identified with $\mathcal{R}_0$, and $U_i$ is lower triangular with $(0,0)$ entry $T_i$. Now $K = \mathcal{K}_0^{(n)}$, and $W = I \oplus U_1 \oplus U_1U_2 \oplus \cdots \oplus (U_1U_2 \cdots U_{n-1})$ is a unitary operator on $K$. $\mathcal{H}$ is identified with $\mathcal{R}_0^{(n)}$ in $K$. The representation $\pi$ is given by

$$\pi([a_{ij}]) = W*[a_{ij}]W = [a_{ij}U_{ij}]$$

where $U_{ij} = U_i \cdots U_{j-1}$ for $i < j$, $U_{ii} = I$, and $U_{ii}^* = U_{ii}^*$ for $i > j$. Because each $U_i$ is a lower triangular,

$$P(\mathcal{R}_0)\pi(E_{ij})|\mathcal{R}_0 = P(\mathcal{R}_0)U_iU_{i+1} \cdots U_{j-1}|\mathcal{R}_0 = T_iT_{i+1} \cdots T_{j+1} = P_i\rho(E_{ij})|\mathcal{H}_j.$$ 

Now $X$ commutes with $A = \rho(E_{12} + E_{23} + \cdots + E_{n-1,n})$. This latter operator has a unitary dilation on $K$ given by

$$U = \begin{bmatrix}
0 & U_1 & 0 & 0 \\
0 & 0 & U_2 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & U_{n-1} \\
U_0 & 0 & 0 & 0
\end{bmatrix}$$

where $U_0$ is the shift mapping $\mathcal{R}_n$ onto $\mathcal{R}_{n+1}$ for all $n$. (Note that $U_0$ is strictly lower triangular.) Apply the Sz-Nagy-Foias Lifting Theorem (Corollary 20.5) to obtain a dilation $Y$ of $X$ on $K$ with $\|Y\| \leq 1$, $YY = UY$, and
\[ P(\mathcal{H})Y^nU^m | \mathcal{H} = X^nA^m \text{ for } n, m \geq 0. \]

Now \( Y \) has an matrix form \((Y_{ij})\), and the commutation relation becomes \( Y_{ij}U_j = U_{i+j}Y_{i+1,j+1} \). In particular, the diagonal part \( D = Y_{11} \oplus \ldots \oplus Y_{nn} \) of \( Y \) also commutes with \( U \). Moreover, \( \mathcal{H} \) is semi-invariant for both \( Y \) and \( U \), and thus \( Y \) and \( D \) both have the form \[
\begin{bmatrix}
* & 0 & 0 \\
* & X & 0 \\
* & * & * 
\end{bmatrix}
\]
and \( U \) has the form \[
\begin{bmatrix}
* & 0 & 0 \\
* & A & 0 \\
* & * & * 
\end{bmatrix}
\]
for the appropriate decomposition of \( K \). This shows that \( D \) also satisfies the dilation identity. So we assume that \( Y = Y_1 \oplus \ldots \oplus Y_n \) is already diagonal.

Next, notice that \( Y \) commutes with \( \pi \). Indeed \( Y \) now commutes with each \( \pi(E_{ii}) \) as it is diagonal, and with each \( \pi(E_{i,i+1}) \) since \( Y_iU_i = U_iY_{i+1} \). This identity implies that \( Y = W^*Y^{(n)}W \) which clearly commutes with \( \pi \). The rest is easy. Dilate \( Y \) to a lower triangular unitary \( V \) on \( K^{(n)} \) as in Theorem 20.1. Dilate \( \pi \) to \( \pi^{(n)} \). Since \( \pi \) is self-adjoint, it commutes with \( Y^* \) as well, and hence \( \pi^{(n)} \) commutes with \( V \). The original space \( \mathcal{H} \) is semi-invariant for both \( V \) and \( \pi^{(n)} \) simultaneously because of the lower triangular forms. Thus the dilation identity holds.

Finally, consider a general nest algebra \( \mathcal{A} \) in \( \mathcal{M}_n \). This contains \( T_n \). Restrict \( \rho \) to \( T_n \) and dilate \( (\rho | T_n, X) \) to \( (\pi, V) \) as above. By the argument in the proof of Theorem 20.14, \( \pi \) dilates \( \rho \). If \( E_{ij} \) belongs to \( \mathcal{A} \) for \( i > j \), then \( T_{ij} = \rho(E_{ij}) \) and \( T_{ji} = \rho(E_{ji}) \) satisfy \( T_{ij}T_{ji} = P_i \) and \( T_{ji}T_{ij} = P_j \). Hence \( T_{ij} = T_{ji}^* \) is a partial isometry. Now the compression of \( \pi \) to \( \mathcal{A} \) is a homomorphism, and thus \( \mathcal{H} \) is semi-invariant for \( \pi(\mathcal{A}) \). Thus, it is a reducing subspace for \( \pi(E_{ij}) \) and \( \pi(E_{ij})^* \). It is also semi-invariant for \( Y \), thus they have the form

\[
\pi(E_{ij}) = \begin{bmatrix}
* & 0 & 0 \\
0 & T_{ij} & 0 \\
* & 0 & * 
\end{bmatrix}
\quad \text{and} \quad
Y = \begin{bmatrix}
* & 0 & 0 \\
* & X & 0 \\
* & * & * 
\end{bmatrix}
\]

from which it is evident that \( P(\mathcal{H})Y^n\pi(E_{ij}) | \mathcal{H} = X^nT_{ij} \). Since the matrix units span \( \mathcal{A} \), \( \pi(\mathcal{V}) \) is the desired dilation.

**20.21 Corollary.** Let \( \mathcal{A} \) be a finite dimensional nest algebra. Suppose that \( \rho: \mathcal{A} \to B(\mathcal{H}) \) and \( \sigma: \mathcal{A}(\mathcal{D}) \to B(\mathcal{H}) \) are commuting contractive representations. Then the representation \( \rho \otimes \sigma \) of \( \mathcal{A} \otimes \mathcal{A}(\mathcal{D}) \) given by

\[
\rho \otimes \sigma([f_{ij}]) = \sum_{i,j} \sigma(f_{ij})\rho(E_{ij})
\]

is completely contractive.
Proof. This is just a reformulation of Theorem 20.20 since \( \sigma \) is determined by the contraction \( X = \sigma(z) \). The dilation obtained is completely positive and unital, hence completely contractive by Lemma 20.6. Thus, the compression to \( \mathcal{H}, \rho \otimes \sigma \), is completely contractive.

Now we extend this result to arbitrary nest algebras.

20.22 Theorem. Let \( \mathcal{N} \) be a nest on a Hilbert space \( \mathcal{K} \). Suppose that \( \rho \) is a weak* continuous contractive representation of \( \mathcal{A} \) on \( \mathcal{N} \) which commutes with a contraction \( X \in B(\mathcal{K}) \). Then there is an isometry \( V \) of \( \mathcal{N} \) into \( \mathcal{R}^{(\omega)} \) and a unitary \( U \) in \( B(\mathcal{R}^{(\omega)}) \) commuting with \( \pi(A) = A^{(\omega)} \) for all \( A \) in \( B(\mathcal{K}) \) such that

\[
V^* U^n \pi(A) V = X^n \rho(A) \text{ for all } n \geq 0, A \in \mathcal{T}(\mathcal{N}).
\]

Proof. Let \( K_1 \) be the C*-algebra \( K + 0 I \), and let \( \mathcal{A} = \mathcal{N} \cap K_1 \). Let \( \mathcal{A}_n, \phi_n \) and \( \psi_n \) be given by Theorem 20.16. The representations \( \tau_n \) of \( \mathcal{A}_n \otimes A(D) \) given by

\[
\tau_n(\{f_{ij}\}) = \sum_{i,j} f_{ij}(X)\rho(\psi_n(E_{ij}))
\]

is completely contractive by Corollary 20.21. Define a representation of \( \mathcal{A} \otimes A(D) \) by \( \tau\left(\sum_{i=1}^N K_i \otimes f_i\right) = \sum_{i=1}^N f_i(X)\rho(K_i) \). (The norm on \( \mathcal{A} \otimes A(D) \) is given by the unique C* norm on \( K_1 \otimes C(T) \).) Now \( K = \lim \psi_n(\phi_n(K)) \) for \( K \) compact by Theorem 20.16, and \( \rho(\psi_n(\phi_n(I))) = \rho(I) \). Thus

\[
\tau(\sum_{i=1}^N K_i \otimes f_i) = \lim_{n \to \infty} \tau_n \circ (\phi_n \otimes \text{id}) (\sum_{i=1}^N K_i \otimes f_i).
\]

Now \( \phi_n \otimes \text{id} \) is just a compression to \( K_N \) and thus is completely contractive, and \( \tau_n \) is completely contractive, hence \( \tau \) is completely contractive. So \( \tau \) extends to all of \( \mathcal{A} \otimes A(D) \).

By Arveson's Dilation Theorem 20.13, \( \tau \) has a \( K_1 \otimes C(T) \) dilation \( \tilde{\tau} \) given by a * representation \( \pi \) of \( K_1 \), and a commuting unitary operator \( U = \tilde{\tau}(z) \) such that

\[
P(\mathcal{H})U^* \pi(K)|\mathcal{H} = X^* \rho(K) \text{ for all } n \geq 0, \text{ and } K \in \mathcal{A}.
\]

The representation \( \pi_1 \) splits into a direct sum \( \pi = \pi_a \oplus \pi_s \) on \( \mathcal{H}_a \oplus \mathcal{H}_s \), where \( \pi_a \) is faithful on \( \mathcal{K} \) and \( \pi_s \) annihilates \( \mathcal{K} \). Since \( U \) commutes with \( \pi_1 \), it decomposes as \( U = U_a \oplus U_s \). The weak* continuity of \( \rho \) implies that \( \mathcal{H} \) is contained in \( \mathcal{H}_a \). For if \( E_n \) is an increasing sequence of projections in \( \mathcal{K} \) tending weak* to the identity, then for \( h \) in \( \mathcal{H} \),

\[
h = w-\lim \rho(E_n)h = w-\lim P(\mathcal{H})\pi(E_n)h = P(\mathcal{H})P(\mathcal{H}_a)h.
\]
Thus, by restricting to $\mathcal{H}_0$, we may assume that $\pi$ is faithful on $K$ and this is an ampliation $\pi(K) = K^{(n)}$. If $n < \infty$, this can be trivially dilated to $n = \infty$ by setting $U = I$ on the extra summands. Thus $\mathcal{H}$ is identified via an isometry $V$ with a subspace of $R^{(n)}$ such that

$$P(\mathcal{H})U^m\pi(K) | \mathcal{H} = X^n \rho(K) \quad \text{for} \quad n \geq 0, K \in A.$$ 

Now both sides are weak* continuous and $A$ is weak* dense in $T(\mathcal{N})$ by Theorem 3.11, so this dilation identity extends to all $T$ in $T(\mathcal{N})$. ■

This analogue of Ando's Theorem yields the corresponding version of the Sz-Nagy-Foias Lifting Theorem.

**20.23 Corollary.** Let $\mathcal{H}$ be a nest of subspaces of $R$. Suppose that $\rho$ is a weak* continuous contractive representation of $T(\mathcal{N})$ on $\mathcal{H}$, and let $\pi$ be a weak* continuous dilation to $B(R)$ on $K$. If $X$ is an operator on $\mathcal{H}$ commuting with $\rho$, then there is an operator $Y$ on $K$ commuting with $\pi$ such that $\|Y\| = \|X\|$ and

$$P(\mathcal{H})Y^m\pi(A) | \mathcal{H} = X^n \rho(A) \quad \text{for} \quad n \geq 0 \quad \text{and} \quad A \in T(\mathcal{N}).$$

**Proof.** Normalize so that $\|X\| = 1$. Let $(\pi_k, U_k)$ be the dilation of $(\rho, K)$ provided by Theorem 20.22. Let $K_0$ be the smallest reducing subspace for $\pi_1$ containing $\mathcal{H}$. Then $\pi_0 = \pi_1 | K_0$ is, by Proposition 20.19, the unique minimal dilation of $\rho$. Let $Y_0$ be the compression of $U$ to $K_0$. Clearly, $Y_0$ is a contraction commuting with $\pi_0$, and $P(\mathcal{H})U | \mathcal{H} = X$.

Now, $\mathcal{H}$ is semi-invariant for $(\pi(T(\mathcal{N})), U)$. Let $K^+$ denote the smallest subspace of $K$ containing $\mathcal{H}$ and invariant for $\pi(T(\mathcal{N}))$ and $U$. Similarly, let $K^-$ denote the smallest subspace containing $\mathcal{H}$ invariant for $\pi(T(\mathcal{N}))^*$ and $U^*$. Let $\mathcal{H}^+$ and $\mathcal{H}^-$ be the smallest subspaces of $K^+$ and $K^-$ respectively which contain $\mathcal{H}$ and are invariant for $\pi(T(\mathcal{N}))$. Then $\pi | T(\mathcal{N})$ has the form

$$\begin{bmatrix} * & 0 & 0 \\ * & 0 & 0 \\ * & X & 0 \end{bmatrix}$$

and $U$ has the form

$$\begin{bmatrix} * & 0 \\ * & 0 \\ * & * & * \end{bmatrix}$$

with respect to the decomposition $(K^+)^\perp \oplus \mathcal{H} \oplus (K^- \ominus \mathcal{H})$.

We wish to show that $K_0 = (\mathcal{H} \ominus \mathcal{H}) \oplus \mathcal{H} \oplus \mathcal{H}^+$. To this end, it suffices to show that $\mathcal{H}^+ + \mathcal{H}^+$ is $\pi$-invariant. As $\pi$ is weak* continuous, it suffices to show that $\mathcal{H}^+ + \mathcal{H}^+$ is invariant for $\pi(F)$ where $F$ is finite rank. Let $\pi(T)h$, for $T$ in $T(\mathcal{N})$ and $h$ in $\mathcal{H}$, be a typical element in the spanning set of $\mathcal{H}^+$. Then $FT$ is finite rank and thus splits as a sum $FT = K_1 + K_2$ where $K_i$ are compact operators in $T(\mathcal{N})$ (Theorem 4.10). So

$$\pi(F)\pi(T)h = \pi(K_1)h + \pi(K_2)h \in \mathcal{H}^+ + \mathcal{H}^-.$$ 

So $K_0$ decomposes as claimed.
This decomposition implies that we have the lower triangular forms

\[
\pi_0 | T(\mathcal{H}) = \begin{bmatrix} * & 0 & 0 \\ * & \rho & 0 \\ * & * & * \end{bmatrix} \quad \text{and} \quad Y_0 = \begin{bmatrix} * & 0 & 0 \\ * & X & 0 \\ * & * & * \end{bmatrix}.
\]

Hence the dilation identity holds:

\[
P(\mathcal{H})Y^n\pi(A)|\mathcal{H} = X^n\rho(A) \quad \text{for} \quad n \geq 0 \quad \text{and} \quad A \in T(\mathcal{H}).
\]

For the general case, decompose \( \pi \) as \( \pi_0 \oplus \pi' \) where \( \pi_0 \) is the minimal dilation of \( \rho \). Dilate \( X \) to \( Y_0 \oplus 0 \). This completes the proof. \( \blacksquare \)

20.24 Remark. A simple but useful trick generalizes this theorem to the case of an operator \( X \) in \( B(\mathcal{H}_1, \mathcal{H}_1) \) intertwining two representations \( \rho_i \) on \( \mathcal{H}_i, i=1,2 \) (i.e., \( \rho_i(A)X = X\rho_i(A) \) for all \( A \) in \( T(\mathcal{H}) \)). Suppose that \( \pi_i \) is a dilation of \( \rho_i \) on \( K_i, i=1,2 \). Then \( \rho_1 \oplus \rho_2 \) is a representation of \( T(\mathcal{H}) \) in \( \mathcal{H}_1 \oplus \mathcal{H}_2 \) with dilation \( \pi_1 \oplus \pi_2 \) on \( K_1 \oplus K_2 \). The operator \( \tilde{X} = \begin{bmatrix} 0 & X \\ 0 & 0 \end{bmatrix} \) commutes with \( \rho_1 \oplus \rho_2 \), and thus there is an operator \( \tilde{Y} \) on \( K_1 \oplus K_2 \) which commutes with \( \pi_1 \oplus \pi_2 \) and dilates \( \tilde{X} \). Clearly, there is no loss in compressing \( \tilde{Y} \) to its (1,2) entry, so we may suppose \( \tilde{Y} = \begin{bmatrix} 0 & Y \\ 0 & 0 \end{bmatrix} \). Thus, \( Y \) intertwines \( \pi_1 \) and \( \pi_2 \) in that \( \pi_i(B)Y = Y\pi_i(B) \) for all \( B \) in \( B(\mathcal{K}) \). The triangular form obtained in the proof above shows that each \( K_i \) decomposes as \( K_i^- \oplus \mathcal{H}_i \oplus K_i^+ \) so that \( \pi_i | T(\mathcal{H}) \) is lower triangular, and \( Y \) has the form \( \begin{bmatrix} * & 0 & 0 \\ * & X & 0 \\ * & * & * \end{bmatrix} \) in \( B(\mathcal{K}_2, \mathcal{K}_1) \). This decomposition is canonical if we insist that \( K_i^+ \oplus \mathcal{H}_i \) be the smallest \( \pi_i | T(\mathcal{H}) \) invariant subspace containing \( \mathcal{H}_i \).

Now we turn to commuting representations of nest algebras.

20.25 Theorem. Let \( \mathcal{A}_1 \) and \( \mathcal{A}_2 \) be nest subalgebras of \( B(\mathcal{K}_1) \) and \( B(\mathcal{K}_2) \). Let \( \rho_1 \) and \( \rho_2 \) be weak* continuous contractive representations of \( \mathcal{A}_1 \) and \( \mathcal{A}_2 \) on a common space \( \mathcal{H} \) such that

\[
\rho_1(A_1)\rho_2(A_2) = \rho_2(A_2)\rho_1(A_1) \quad \text{for all} \quad A_1 \in \mathcal{A}_1, A_2 \in \mathcal{A}_2.
\]

Then there is a Hilbert space \( K \) containing \( \mathcal{H} \), weak* continuous \( B(\mathcal{K}_1) \)-dilations \( \pi_i \) of \( \rho_i \) on \( \mathcal{H}, i=1,2 \), such that

\[
P(\mathcal{H})\pi_1(A_1)\pi_2(A_2)|\mathcal{H} = \rho_1(A_1)\rho_2(A_2) \quad \text{for} \quad A_1 \in \mathcal{A}_1, A_2 \in \mathcal{A}_2
\]

and

\[
\pi_1(B_1)\pi_2(B_2) = \pi_2(B_2)\pi_1(B_1) \quad \text{for} \quad B_1 \in B(\mathcal{K}_1), B_2 \in B(\mathcal{K}_2).
\]
Proof. Assume first that \( \mathbb{A}_2 \) is the upper triangular algebra \( \mathcal{T}_n \) contained in \( \mathcal{M}_n \). Let the standard matrix units for \( \mathcal{M}_n \) be \( E_{ij} \). Now \( \rho_1 \) commutes with \( P_j = \pi(E_{jj}) \) for \( 1 \leq j \leq n \). This decomposes \( \rho_1 \) as \( \sum_{j=1}^{n} \bigoplus \rho_{1,j} \) on \( \mathcal{H} = \sum_{j=1}^{n} \mathcal{H}_j \). Let \( \pi_1 = \sum_{j=1}^{n} \bigoplus \pi_{1,j} \) be a weak* continuous \( B(\mathcal{K}_1) \) dilation of \( \rho_1 \) on \( \mathcal{K} = \sum_{j=1}^{n} \bigoplus \mathcal{K}_j \). Now \( T_j = P_j \rho_2(E_{i,i+1}) \mathcal{H}_j \bigoplus \mathcal{K}_j \) intertwines \( \rho_{1,j} \) and \( \rho_{1,j+1} \). By Remark 20.24, there are contractions \( Y_j \) in \( B(\mathcal{K}_{j+1}) \) which intertwine \( \pi_{1,j} \) and \( \pi_{1,j+1} \) and dilate \( X_j \). The triangular form of \( Y_j \) is crucial. Each \( \mathcal{K}_j \) decomposes as \( \mathcal{K}_j^\perp \bigoplus \mathcal{H}_j \bigoplus \mathcal{K}_j^\perp \) where \( \mathcal{H}_j \bigoplus \mathcal{K}_j^\perp \) is the smallest subspace containing \( \mathcal{H}_j \) invariant for \( \pi_{1,j} \bigoplus \mathcal{A}_1 \). Considering \( Y_j \) as an operator from \( \mathcal{K}_{j+1} \) to \( \mathcal{K}_j \) and \( \pi_{1,j} \bigoplus \mathcal{A}_1 \) as a representation on \( \mathcal{K}_j \) with this decomposition, we obtain the triangular forms

\[
Y_j = \begin{bmatrix}
* & 0 & 0 \\
* & T_j & 0 \\
* & * & *
\end{bmatrix} \quad \text{and} \quad \pi_{1,j} \bigoplus \mathcal{A}_1 = \begin{bmatrix}
* & 0 & 0 \\
* & \rho_{1,j} & 0 \\
* & * & *
\end{bmatrix}.
\]

Now consider each \( Y_j \) as an operator on \( \mathcal{K} \). The triangular form implies

\[
P(\mathcal{H}) Y_i Y_{i+1} \ldots Y_{j-1} \mathcal{H} = \rho_2(E_{ij}) \quad \text{for} \quad 1 \leq i < j \leq n_2.
\]

Thus, \( Y_1, \ldots, Y_{n_2-1} \) determine a representation \( \pi_2 \) of \( \mathcal{T}_n \) on \( \mathcal{K} \) which dilates \( \rho_2 \) commutes with the representation \( \pi_1 \) of \( B(\mathcal{K}_1) \). As usual, it is now easy to dilate the rest of the way up. Let \( \sigma_2 \) be the \( \mathcal{M}_n \) dilation of \( \pi_2 \) constructed on \( \mathcal{K}^{\text{opp}} \) as in Theorem 20.14. Since \( \pi_1 \) is a \( \ast \)-representation, it commutes with \( \mathcal{K}^{\text{opp}}_n \) also, and hence \( \sigma_1 = \pi_1^{\text{opp}} \) is an \( B(\mathcal{K}_1) \) dilation of \( \pi_1 \) commuting with \( \sigma_2 \). It is clear that \( \sigma_1 \otimes \sigma_2 \) dilates \( \rho_1 \otimes \rho_2 \) and thus the dilation identities hold.

Next, suppose that \( \mathbb{A}_2 \) is a general nest subalgebra of \( \mathcal{M}_n \) containing \( \mathcal{T}_n \). Dilate \( \rho_1 \otimes (\rho_2 \bigoplus \mathcal{T}_n) \) to a \( B(\mathcal{K}_1) \otimes \mathcal{M}_n \) representation \( \sigma_1 \otimes \sigma_2 \). The compression of \( \sigma_1 \otimes \sigma_2 \) to \( \mathcal{H} \) is the unique (completely) positive extension of \( \rho_1 \otimes (\rho_2 \bigoplus \mathcal{T}_n) \) and hence agrees with \( \rho_2 \otimes \rho_2 \) on \( \mathcal{A}_1 \otimes \mathcal{A}_2 \). The restriction of \( \rho_2 \) to \( \mathcal{A}_2 \bigoplus \mathcal{A}_2 \) is a \( \ast \) representation with dilation \( \sigma_2 \), and hence \( \mathcal{H} \) is invariant for \( \sigma_2(\mathcal{A}_2 \bigoplus \mathcal{A}_2) \). So as in the proof of Theorem 20.20, we see that \( \sigma_1 \bigoplus \mathcal{A}_1 \) and \( \sigma_2 \bigoplus \mathcal{A}_2 \) have the forms

\[
\sigma_1 \bigoplus \mathcal{A}_1 = \begin{bmatrix}
* & 0 & 0 \\
* & \rho_1 & 0 \\
* & * & *
\end{bmatrix} \quad \text{and} \quad \sigma_2 \bigoplus \mathcal{A}_2 = \begin{bmatrix}
* & 0 & 0 \\
0 & \rho_2 & 0 \\
* & * & *
\end{bmatrix}.
\]

Hence the dilation identity follows for each matrix unit \( E_{ij} \) in \( \mathcal{A} \) with \( i > j \).
Finally, let $\mathcal{A}_n$ be a nest algebra $\mathcal{T}(\mathcal{N})$ and proceed as in Theorem 20.22. Let $K = K + CI$, $\mathcal{A} = \mathcal{T}(\mathcal{N}) \cap K_I$; and let $\mathcal{A}_n$, $\phi_n$ and $\psi_n$, $n \geq 3$, be given by Theorem 20.16. The representations $\rho_1 \otimes (\rho_2 \circ \psi_n)$ of $\mathcal{A}_1 \otimes \mathcal{A}_n$ have dilations and thus are completely contractive. Every $K_n$ in $\mathcal{A}$ has the property that $\rho_2(K_n) = \lim_{n \to \infty} \rho_2(\phi_n(K_n))$ and all maps are completely contractive. Thus, it follows that $\rho_1 \otimes (\rho_2 | A)$ is completely contractive. By Theorem 20.13, this has a $B(\mathcal{H}_n) \otimes B(\mathcal{K}_n)$ dilation $\pi_1 \otimes \pi_2$. As before, the weak* continuous part is itself a dilation of $\rho_1 \otimes (\rho_2 | A)$. The weak* continuity shows that it is a dilation of $\rho_1 \otimes \rho_2$.

20.26 Remark. Proceeding as in the proof of Theorem 20.23, we can establish a Sz. Nagy-Foias Lifting Theorem for nests. Namely, if $\rho_1$ and $\rho_2$ are commuting, weak* continuous, contractive representations of $\mathcal{T}(\mathcal{M}_1)$ and $\mathcal{T}(\mathcal{M}_2)$ on $\mathcal{H}_1$ and if $\pi$ is a $B(\mathcal{K})$ dilation of $\rho_1$ on $K$, then there is a weak* continuous contractive representation $\sigma$ of $\mathcal{T}(\mathcal{M}_2)$ on $K$ commuting with $\pi$ such that

$$F(\mathcal{H})\pi(A_1)\sigma(A_2) | \mathcal{H} = \rho_1(A_1)\rho_2(A_2)$$

for $A_1 \in \mathcal{T}(\mathcal{M}_1)$, $A_2 \in \mathcal{T}(\mathcal{M}_2)$.

20.27 Examples. We finish this chapter with examples of Parrott and Paulsen which demonstrate that the dilation theorems do not work for triples. Let

$$U = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix} \quad \text{and} \quad V = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix},$$

and note that $UV + VU = 0$. Consider the three commuting $4 \times 4$ contractions

$$T_1 = \begin{bmatrix} 0 & I_2 \\ 0 & 0 \end{bmatrix}, \quad T_2 = \begin{bmatrix} 0 & U \\ 0 & 0 \end{bmatrix}, \quad \text{and} \quad T_3 = \begin{bmatrix} 0 & V \\ 0 & 0 \end{bmatrix}.$$

If $(T_1, T_2, T_3)$ had a commuting unitary dilation $(U_1, U_2, U_3)$, then the associated representation $\rho_1 \otimes \rho_2 \otimes \rho_3$ of $\mathcal{A}(\mathcal{D}^3)$ would be completely contractive. Consider the matrix function

$$F(z_1, z_2, z_3) = \begin{bmatrix} z_1 & z_2 & 0 \\ z_3 & 0 & z_2 \\ 0 & z_3 & -z_1 \end{bmatrix}.$$
Representations and Dilations

\[
\|F(x_1, x_2, x_3)\| = \left\| \begin{bmatrix}
  z_1 & 0 & 0 \\
  0 & z_3 & 0 \\
  0 & 0 & z_3z_2z_1
\end{bmatrix} \begin{bmatrix}
  1 & 1 & 0 \\
  1 & 0 & 1 \\
  0 & z_1z_2 & 0
\end{bmatrix} \begin{bmatrix}
  1 & 0 & 0 \\
  0 & 0 & \bar{z}_2 \\
  0 & 0 & \bar{z}_3z_2
\end{bmatrix} \right\|.
\]

The first and third matrices are unitary on the Shilov boundary \( T^3 \), and hence

\[
F(I, U, V) = \begin{bmatrix}
  I & U & 0 \\
  V & 0 & U \\
  0 & V & -I
\end{bmatrix} = \begin{bmatrix}
  I & 0 & 0 \\
  0 & V & 0 \\
  0 & 0 & V^*U
\end{bmatrix} \begin{bmatrix}
  I & I & 0 \\
  0 & I & 0 \\
  0 & 0 & I
\end{bmatrix} = \begin{bmatrix}
  I & 0 & 0 \\
  0 & U & 0 \\
  0 & 0 & VU
\end{bmatrix}.
\]

Again, the first and third entries are unitary, so

\[
\|F(T_1, T_2, T_3)\| = \|F(I, U, V)\| = \left\| \begin{bmatrix}
  1 & 1 & 0 \\
  1 & 0 & 1 \\
  0 & 1 & 1
\end{bmatrix} \right\| = 2 > \sqrt{3}.
\]

Hence \( \rho_2 \otimes \rho_2 \otimes \rho_3 \) is not completely contractive.

It is true that \( \|\rho_1 \otimes \rho_2 \otimes \rho_3\| = 1 \). To briefly outline this, note that all products of any two of \( T_1, T_2, T_3 \) is in 0. Thus, if \( f(z) = a_0 + \sum_{i=1}^3 a_i z_i + r(z) \), where \( r(z) \) has no constant or linear terms, then

\[
f(T_1, T_2, T_3) = \begin{bmatrix}
  a_0I & a_1I + a_2U + a_3V \\
  0 & a_0I
\end{bmatrix}.
\]

Computing \( \left( f(T_1, T_2, T_3) \begin{bmatrix} x_1 \\ y_1 \end{bmatrix}, \begin{bmatrix} y_2 \\ z_2 \end{bmatrix} \right) \) and straightforward estimates yields

\[
\|F(T_1, T_2, T_3)\| \leq \left\| \begin{bmatrix}
  |a_0| & \sum_{i=1}^3 |a_i| \\
  0 & |a_0|
\end{bmatrix} \right\|.
\]

This is a compression of the Laurent operator \( g(z) = |a_0| + (\sum_{i=1}^3 |a_i|)z + h(z)z^2 \) to a 2x2 block, and hence

\[
\|f(T_1, T_2, T_3)\| \leq \inf_{h \in A(D)} \|a_0 + \sum_{i=1}^3 |a_i| |z + h(z)z^2\| \leq \|f\|_{\infty}.
\]

Now we will use this example to construct three commuting, contractive, unital representations of the triangular algebra \( T_2 \) which do not dilate to commuting \( M_2 \) representations. These representations will be unitarily equivalent to
\[
\sigma_i \begin{bmatrix} a & b \\ 0 & d \end{bmatrix} = \begin{bmatrix} aI_4 & bT_i \\ 0 & dI_4 \end{bmatrix}^{(i)}
\]

For economy, we mark the non-zero entries of a typical element \( A \) of \( \mathcal{A} = \mathcal{T}_2 \otimes \mathcal{T}_2 \otimes \mathcal{T}_2 \) and a representation \( \sigma \) of \( \mathcal{A} \) given by Schur multiplication \( \langle [a_{ij} \circ [b_{ij}] = [a_{ij}b_{ij}] \rangle \) by an operator matrix \( T \).

\[ A = \begin{bmatrix}
* & * & * & * & * & * \\
* & * & * & * & * & * \\
* & * & * & * & * & * \\
* & * & * & * & * & * \\
* & * & * & * & * & * \\
* & * & * & * & * & *
\end{bmatrix}
\quad \text{and}
\quad T = \begin{bmatrix}
I_4 & T_1 & T_2 & 0 & T_3 & 0 & 0 & 0 \\
I_4 & T_1 & T_2 & T_3 & 0 & 0 & 0 & 0 \\
I_4 & T_1 & T_2 & T_3 & 0 & 0 & 0 & 0 \\
I_4 & T_1 & T_2 & T_3 & 0 & 0 & 0 & 0 \\
I_4 & T_1 & T_2 & T_3 & 0 & 0 & 0 & 0 \\
I_4 & T_1 & T_2 & T_3 & 0 & 0 & 0 & 0
\end{bmatrix}
\]

The fact that \( T_iT_j = 0 \) for all \( i,j \) leads to the fact that \( \sigma \) is multiplicative. The three copies of \( \mathcal{T}_2 \) occur in \( \mathcal{A} \) as

\[ \begin{bmatrix}
a & b & \cdots & \cdots & \cdots & \cdots \\
a & d & \cdots & \cdots & \cdots & \cdots \\
a & a & b & \cdots & \cdots & \cdots \\
a & d & \cdots & \cdots & \cdots & \cdots \\
a & a & b & \cdots & \cdots & \cdots \\
a & d & \cdots & \cdots & \cdots & \cdots 
\end{bmatrix}, \quad \text{and}
\begin{bmatrix}
a & b & \cdots & \cdots & \cdots & \cdots \\
a & a & b & \cdots & \cdots & \cdots \\
a & d & \cdots & \cdots & \cdots & \cdots \\
a & a & b & \cdots & \cdots & \cdots \\
a & d & \cdots & \cdots & \cdots & \cdots \\
a & d & \cdots & \cdots & \cdots & \cdots 
\end{bmatrix}
\]

respectively. The representation \( \sigma_i \) are all contractive. To show that the \( \sigma_i \) do not jointly dilate, it suffices to show that \( \sigma \) is not contractive. To this end, we define the following element \( A_0 \) in \( \mathcal{A} \).

\[ A_0 = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & -1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 
\end{bmatrix}, \quad \text{and}
\[ \sigma(A_0) = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & T_2 & 0 & T_3 & 0 & 0 \\
0 & 0 & 0 & T_1 & 0 & 0 & T_3 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & T_1 & -T_2 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 
\end{bmatrix}
\]

Then as before, we obtain \( \|A_0\| = \sqrt{3} \) and \( \|\sigma(A_0)\| = 2 \).
Notes and Remarks.

Classical dilation theory is developed in detail in the book by Sz. Nagy and Foias [2], and in the briefer monograph by Sz. Nagy [2]. A nice treatment of completely positive maps and the algebraic approach to dilation theory is in Paulsen [1]. Theorem 20.1 is due to Sz. Nagy [1]. Theorem 20.4 is taken from Ando [1]. Corollary 20.5 is a strengthened form of Sz. Nagy and Foias [1] due to Parrott [2]. Completely positive maps are introduced in Stinespring [1], where Theorem 20.12 is proved. This theory was developed extensively by Arveson [4,5]. In particular, he proves 20.7, 20.8, Theorems 20.10 and Corollary 20.13. The proof of Theorem 20.10 based on Lemma 20.9 is taken from Paulsen [1].

The material on representations of nest algebras is taken from Paulsen, Power and Ward [1]. However, Theorem 20.14 was known, and is a special case of results of McAsey and Muhly [1]. They investigate certain non self-adjoint subalgebras of crossed products of C*-algebras and von Neumann algebras. (For more information in this direction, see papers in the references by McAsey, Muhly, Saito and Solel.) The lifting theorems for nests are due to Paulsen and Power [1]. The finite dimensional case of Corollary 20.23 is due to Ball and Gohberg [2] who exhibit all operators Y commuting with π such that \( \|Y\| = \|X\| \) and \( P(\mathcal{N})Y = X \). Example 20.27 is due to Parrott [1]. The extension of this example to commuting representations of \( T_2 \) is due to Paulsen.

Exercises.

20.1 Verify that the unitary dilation of \( A \) constructed in Theorem 20.1 also satisfies \( P(\mathcal{N})U^n \mathcal{N} = A^n \mathcal{N} \) for \( n \geq 0 \).

20.2 (a) There is a notion of isometric dilation of a contraction. Show that there is a unique minimal isometric dilation of \( A \), given by restricting its minimal unitary dilation \( U \) to \( K^+ = \bigvee_{n \geq 0} U^n \mathcal{N} \).

(b) Prove the analogue of the Sz. Nagy-Foias lifting theorem for isometric dilations.

20.3 Suppose \( A_i \) are contractions on \( \mathcal{H}_i \) with unitary dilations \( U_i \) on \( K_i \). If \( X \) is a map in \( B(\mathcal{H}_2, \mathcal{H}_1) \) such that \( A_1 X = X A_2 \), show that there is a map \( Y \) in \( B(K_2, K_1) \) such that \( U_1 Y = Y U_2 \), \( \|Y\| = \|X\| \), and \( F(\mathcal{N})Y \mathcal{N} = X \).

20.4 Prove that if \( \phi \) is a completely positive map from a C*-algebra \( \mathcal{A} \) into a C*-algebra \( \mathcal{B} \), then

\[
\phi(A)^* \phi(A) \leq \phi(A^* A) \quad \text{for all} \quad A \in \mathcal{A}.
\]

Hint: Dilate \( \phi \) using Stinespring’s Theorem.
20.5 Prove that there is a unique minimal Stinespring dilation of a completely positive map up to the natural unitary equivalence.

20.6 Let $\phi$ be a map from a $C^*$-algebra $\mathcal{A}$ into $\mathcal{M}_n$ such that $\phi^{(n)}$ is positive. Show that $\phi$ is completely positive. Hint: Examine the proof of Lemma 20.9.

20.7 Prove the lifting theorem for commuting representations of nests outlined in Remark 20.26.

20.8* If $\phi$ is a bounded representation of a nest algebra, is $\|\phi\|_{cb} = \|\phi\|$?
21. Operators in Nest Algebras

In this chapter, we survey two aspects of single operator theory related to nests. The first concerns the structure of unicellular operators. The second concerns which operators are unitarily equivalent to (small) compact perturbations of a fixed nest algebra. This does not contain a complete account of either topic, but should serve as a useful introduction to the ideas involved.

21.A Unicellular Operators. An operator $T$ is unicellular if $\text{Lat } T$ is a nest. It is an open problem to discover which maximal nests are the invariant subspace lattice of a single operator. (Such lattices are called attainable.) Theorem 5.5 shows that the Volterra operator $V$ is unicellular. Thus the Volterra nest is an attainable lattice. By the Similarity Theorem, every continuous nest is attainable as the lattice of an operator similar to $V$. The simplest case is an atomic nest of order type $\omega + 1 = \mathbb{N} \cup \{\infty\}$ or $(\omega+1)^* = \{-\infty\} \cup -(\mathbb{N})$.

21.1 Proposition. Let $S$ be a backward shift on a basis $\{e_n, n \geq 0\}$ given by $Se_0 = 0$ and $Se_n = w_n e_{n-1}$ for $n \geq 1$. Suppose that $w_n$ are positive, monotone decreasing, and belong to $\ell^p$ for some $p < \infty$. Then $S$ is unicellular, and

$$\text{Lat } S = \{M_n = \text{span } \{e_k, k \leq n\} : n \geq 0\}.$$ 

Proof. It is clear that each $M_n$ is invariant for $S$. Also, if $x = \sum_{n=0}^{\infty} a_n e_n$, then the cyclic invariant subspace of $S$ generated by $x$ is precisely $M_n$. As $\bigcup_n M_n$ is dense in $\mathcal{H}$, it suffices to show that if $x = \sum_{n \geq 0} a_n e_n$ does not belong to any $M_n$, then $L(x) = \text{span } \{S^n x, n \geq 0\}$ equals $\mathcal{H}$.

First we show that $e_0$ belongs to $L(x)$. Fix an integer $n_0 > p$; and define $w_k^{(n_0)} = \prod_{j=1}^{n_0} w_{k+j}$. This is summable, so let $C = \sum_{k \geq 0} w_k^{(n_0)}$. Given $\epsilon > 0$, pick $n > n_0$ so that $w_n < \epsilon C^{-1} w_0^{(n+1)}$ and $|a_n| \geq \sup_{k>n} |a_k|$. Then
\[
(a_n \prod_{j=1}^{n} w_j)^{-1} S^n x - e_0 = \sum_{k \geq 1} \frac{a_{n+k}}{w_n} \prod_{j=1}^{n} \frac{w_{j+k}}{w_j} e_k.
\]

Now for all \( k \geq 1 \),
\[
\prod_{j=1}^{n} \frac{w_{j+k}}{w_j} = \frac{w_k^{(n)}}{w_1^{(n)}} \cdot \prod_{j=a_0+1}^{n-l} \frac{w_{j+k}}{w_{j+1}} \cdot \frac{w_{n+k}}{w_{n_0+1}} < w_k^{(n)} \cdot \frac{w_{n+1}}{w_0^{(a_0+1)}} < \frac{\epsilon}{C} w_k^{(n)}.
\]

Hence
\[
\|(a_n w_0^{(n)})^{-1} S^n x - e_0\| \leq \frac{\epsilon}{C} \sum_{k \geq 1} w_k^{(n)} < \epsilon.
\]

Suppose \( M_n \) is contained in \( L(x_0) \). Write \( \mathcal{H} = M_n \oplus M_n^\perp \) and \( L(x) = M_n \oplus L_n(x) \). Then \( L_n(x) \) is invariant for the compression \( S_n \) of \( S \) to \( M_n^\perp \). Since \( S_n \) satisfies the same hypotheses as \( S \), \( L_n(x) \) contains \( e_{n+1} \). By induction, \( L(x) \) contains all \( \{e_n, n \geq 0\} \) and hence equals \( \mathcal{H} \).

To build more complicated unicellular operators, one requires a method for gluing them together. This is provided by the following theorem. By the ordinal sum \( L + M \) of two subspace lattices \( L \) and \( M \), we mean \( \{L \oplus 0 : L \in L\} \cup \{0 \oplus M : M \in M\} \).

**21.2 Theorem.** Suppose \( S \) is an operator with cyclic vector \( g \) such that for some \( s > 0 \), \( \|S^n\| = O((n!)^{-s}) \). Let \( A \) be any unilateral weighted shift with weights \( w_n \) monotone decreasing and in \( \ell_p \) for some \( p < \infty \) such that
\[
\|S^n\| = O(\|A^{n+1}\|) \text{ for all } n \geq 0.
\]

Then there is an operator \( T \) of the form
\[
\begin{bmatrix}
S & C \\
0 & A
\end{bmatrix}
\]
such that \( \text{Lat } T = \text{Lat } S^+(w+1)^\ast \), and \( T \) has a cyclic vector.

**21.3 Remarks.** This condition can be achieved by choosing \( 0 < r < s \) and taking \( w_n = n^{-r} \), so that \( \|A^n\| = (n!)^{-r} \). From Stirling's formula
\[
((n!)^{-s}) = O(((n+k)!)^{-s}) \text{ for all } n \geq 0.
\]

This norm condition implies a stronger version of itself, namely
\[
\|S^n\| = O(n^{-1}\|A^{n+k}\|) \text{ for all } n \geq 0.
\]

To see this, note that because \( w_n \) is a monotone decreasing summable sequence, \( \lim_{n \to \infty} n w_n = 0 \). Hence
\[ \|A^{n+k+p}\| \leq w_n^p\|A^{n+k}\| = O(n^{-1}\|A^{n+k}\|). \]

Consequently,
\[ \|S^n\| = O(\|A^{n+k+p}\|) = O(n^{-1}\|A^{n+k}\|). \]  \hspace{1cm} (21.2.1)

In fact, this shows that \( \|S^n\|/\|A^{n+k}\| = O(w_n^p) \). Hence
\[ \sum_{n \geq 1} \|S^n\|/\|A^{n+k}\| < \infty \text{ for all } k \geq 0. \]

To set the stage for the proof of Theorem 21.2, we describe the construction of \( C \). For convenience, normalize \( S, A \) and \( g \) to have norm one. Choose a summable sequence \( c_n \) of positive real numbers such that
\[ \lim_{n \to \infty} c_n^{-1}(\sum_{m \geq n} c_m) = 0. \]

For example, one could take \( c_n = (n!)^{-1} \). Now choose an increasing sequence of positive integers \( k_n \) such that
\[ \lim_{n \to \infty} c_n^{-1}w_{k_n} = 0 \quad \text{and} \quad \lim_{n \to \infty} c_n^{-1}k_n S^{k_n-k_n-1} = 0. \]

This choice is made inductively. The first condition follows if \( k_n \) is large enough. The second also follows because of condition (21.2.1). Now define \( C \) by
\[ C = g \otimes \sum_{m \geq 1} c_m e_m^*. \]

21.4 **Lemma.** Let \( T = \begin{bmatrix} S & C \\ 0 & A \end{bmatrix} \) be defined as above. Let \( \lambda_n = (c_n\|A^{k_n}\|^{-1} \) and let \( D = \sum_{n \geq 0} \|A^n\|^{-1}S^n g \otimes e_n^* \). Then
\[ \lim_{n \to \infty} \lambda_n T^{k_n+1} = D. \]

**Proof.** Write
\[ \lambda_n T^{k_n+1} = \begin{bmatrix} \lambda_n S^{k_n+1} & X_n \\ 0 & \lambda_n A^{k_n+1} \end{bmatrix}. \]

Then
\[ \lim_{n \to \infty} \|\lambda_n A^{k_n+1}\| = \lim_{n \to \infty} c_n^{-1}w_{k_n+1} = 0. \]

Since \( \|\lambda_n S^{k_n+1}\| = O(\lambda_n\|A^{k_n+1}\|), \lim_{n \to \infty} \|\lambda_n S^{k_n+1}\| = 0 \) also. A routine computation shows that \( X_n = \lambda_n \sum_{j=0}^{k_n} S^j C A^{k_n-j} \). Set \( C_m = g \otimes c_m e_m^* \) and \( X_{n,m} = \lambda_n \sum_{j=0}^{k_n} S^j C_m A^{k_n-j} \). Clearly, \( C = \sum_{m \geq 1} C_m \) and \( X_n = \sum_{m \geq 1} X_{n,m} \).
Moreover,
\[ S^j C_m A^{k_j - j} = c_m S^j g \otimes (A^{k_j - j} e_{k_m})^* . \]
Thus if \( m < n \), then \( A^j e_{k_m} = 0 \) for \( j < k_n - k_m \). Thus
\[
\| X_{n,m} \| \leq \lambda_n c_m \| \sum_{j=0}^{k_m} S^{k_n - j} g \otimes (A^j e_{k_m})^* \| \\
\leq \lambda_n c_m (k_m + 1) \| S^{k_n - k_m} g \| \| g \|
\leq c_m (c_n^{-1} k_n \| S^{k_n - k_n - 1} \| A^{k_n} \|^{-1}) .
\]
Hence
\[
\lim_{n \to \infty} \sum_{m=1}^{n-1} \| X_{n,m} \| \leq \left( \sum_{m=1}^{\infty} c_m \right) \lim_{n \to \infty} c_n^{-1} k_n \| S^{k_n - k_n - 1} \| A^{k_n} \|^{-1} = 0 .
\]
Next, we have \( \| A^k \|=\|A^k e_k\| \). So \( \| A^{k_n} \|^{-1} \| A^{k_n - j} e_{k_n} \| = \| A^j \|^{-1} \). Thus if \( m > n \),
\[
\| X_{n,m} \| \leq \lambda_n c_m \sum_{j=0}^{k_n} \| S^j \| \| g \| \| A^{k_n - j} e_{k_n} \| \\
\leq c_n^{-1} c_n \sum_{j=0}^{k_n} \| S^j \| \| A^j \|^{-1} .
\]
Hence
\[
\lim_{n \to \infty} \sum_{m=n+1}^{\infty} \| X_{n,m} \| \leq \lim_{n \to \infty} c_n^{-1} \left( \sum_{m=n+1}^{\infty} \sum_{j=0}^{\infty} \| S^j \| \| A^j \|^{-1} \right) = 0 .
\]
Finally, for \( m = n \), \( \| A_{k_n} \|^{-1} A^{k_n - j} e_{k_n} = \| A^j \|^{-1} e_j \). So
\[
X_{n,n} = \lambda_n c_n \sum_{j=0}^{k_n} S^j g \otimes (A^{k_n - j} e_{k_n})^* = \sum_{j=0}^{k_n} \| A^j \|^{-1} S^j g \otimes e_j^* .
\]
Since \( \sum_{j \geq 0} \| A^j \|^{-1} \| S^j \| < \infty \), \( \lim_{n \to \infty} X_{n,n} = D \), and the lemma follows. \( \blacksquare \)

**Proof of Theorem 21.2.** Let \( M \) be an invariant subspace for \( T \). Let \( M_0 = M \cap (\mathcal{H} \oplus 0) \). This is invariant for \( T \), and hence (as a subspace of \( \mathcal{H} \)) is invariant for \( S \). Thus if \( M = M_0 \), then \( M \) belongs to \( \text{Lat} S^+ (\omega + 1)^* \).
If \( M \neq M_0 \), it must be shown that \( M_0 = \mathcal{H} \oplus 0 \). For then, \( M = \mathcal{H} \oplus L \) where \( L \) belongs to \( \text{Lat} A \) which is isomorphic to \( (\omega + 1)^* \) by Proposition 21.1. Whence \( \text{Lat} T = \text{Lat} S^+ (\omega + 1)^* \).

Let \( L \) be the closure of \( P(0 \oplus \mathcal{H})M \). Then \( M \lor (\mathcal{H} \oplus 0) = \mathcal{H} \oplus L \) is invariant for \( T \), and thus \( L \) is a non-zero invariant subspace of \( A \). By Proposition 21.2, there is an integer \( n_0 \) so that \( L = \text{span} \{ e_n, n \geq n_0 \} \). By Lemma 21.5, the operator \( D \) belongs to the norm closed algebra generated
by $T$, and therefore $D$ leaves $M$ invariant. For each $n \geq n_0$, choose $x_k$ in $M$ such that $\lim_{k \to \infty} P(0 \oplus \mathcal{H})x_k = e_n$. Then

$$\|A^n\|^{-1}S^n g = De_n = \lim_{k \to \infty} Dx_k.$$ 

So $M$ contains $\text{span}\{S^n g : n \geq n_0\}$ which has finite codimension in $\mathcal{H} \oplus 0$. As $L$ has finite codimension in $0 \oplus \mathcal{H}$, it follows that $M$ has finite codimension itself.

Let $B$ be the restriction of $T^*$ to $M^\perp$, which is invariant for $T^*$. Now $T$, and hence $T^*$, is quasinilpotent. Since $M^\perp$ is finite dimensional, $B$ is nilpotent; say of order $q$. Then $T^*$ annihilates $M^\perp$, whence the range of $T^*$ is contained in $M$. Choose $m$ so large that $k_m \geq n_0$ and $k_m - k_{m-1} > q$. Then $M$ contains

$$T^*e_{k_m-\gamma+1} = A^*e_{k_m-\gamma+1} + \sum_{j=0}^{q-1} S^jCA^{q-1-j}e_{k_m-\gamma+1}$$

$$= \alpha e_{k_m+1} + \sum_{j=0}^{q-1} S^jC\alpha_j e_{k_m-j} = \alpha e_{k_m+1} + \alpha_0 g,$$

where $\alpha$ and $\alpha_0$ are non-zero constants. Hence $M$ contains $g$ which is cyclic for $S$. So $M$ contains $\mathcal{H} \oplus 0$ and equals $\mathcal{H} \oplus L$ as claimed. ■

### 21.5 Corollary

For any finite non-negative integers $m$ and $n$, the lattice $\omega m+1+(\omega n)^*$ is attainable.

**Proof.** Choose real numbers $p_1 > p_2 > \cdots > p_{n+m} > 0$. Let $A_k$ be the unilateral weighted shift with weights $n^{-p_k}$, so that $\|A_k^n\| = (n!)^{p_k}$. By induction, Theorem 21.2 provides operators $C_k$ so that

$$S = \begin{bmatrix}
A_1 & C_1 & 0 & 0 & 0 \\
0 & A_2 & C_2 & 0 & 0 \\
0 & 0 & A_3 \\
0 & 0 & 0 & A_{m-1} & C_{m-1} \\
0 & 0 & 0 & 0 & A_m
\end{bmatrix}$$

has $\text{Lat} S \cong (\omega m+1)^*$, and $S$ has a cyclic vector. The norm condition is verified in Exercise 21.1. Continue to use Theorem 21.2 to produce $C_{m-1}, ..., C_{n-1}$ so that
\[ T = \begin{bmatrix} S^* & C_m & 0 & 0 & 0 \\ 0 & A_{m+1} & C_{m+1} & 0 & 0 \\ 0 & 0 & 0 & A_{n-1} & C_{n-1} \\ 0 & 0 & 0 & 0 & A_n \end{bmatrix} \]

has \( \text{Lat} \ T = \text{Lat} S + (n \omega + 1)^\ast \cong \omega m + 1 + (\omega n)^\ast \). \hfill \blacksquare

A quite different approach is needed to produce an operator with lattice isomorphic to \((-\infty) \cup \mathbb{Z} \cup (+\infty) = (\omega + 1)^\ast + (\omega + 1)^\ast \). Like the last proof, it is computationally technical.

**21.8 Theorem.** Let \( X \) be a bilateral shift with weights \( w_n > 0 \) given by \( S e_n = w_n e_{n+1} \) for \( n \in \mathbb{Z} \). Let \( \pi_n = \prod_{k=0}^{n-1} w_n \) for \( n \geq 0 \) and \( \pi_n = \prod_{k=1}^{n} w_n \) for \( n < 0 \). Assume that \( \{w_n, n \geq 0\} \) and \( \{w_n, n \leq 0\} \) are monotone decreasing, and that

\[
\limsup_{n \to -\infty} -\frac{\log \pi_n}{n^2} > \gamma > \log 3
\]

and

\[
\liminf_{|n| \to \infty} -\frac{\log \pi_n}{|n|^2} > \delta > 0 .
\]

Then \( \text{Lat} S = \{M_n = \text{span} \{e_k : k \geq n\} : n \in \mathbb{Z}\} \cup \{0, \mathbb{N}\} \).

**Remark.** One can take \( w_n = 10^{-|n|} \) to satisfy the hypotheses of this theorem.

**Proof.** For convenience, normalize \( S \) to be norm one. Since \( \mathcal{H} = \{M_n, n \in \mathbb{Z}; 0, \mathbb{N}\} \) is a complete lattice, it suffices to show that every cyclic invariant subspace for \( S \) is in \( \mathcal{H} \). The conditions on the weights show that \( \pi_n < e^{-n^2/2} \) for \( |n| \) large. Since \( w_n \) is monotone,

\[
w_n \leq \pi_n^{1/|n|} < e^{-n\delta}
\]

for \( |n| \) large. Hence the weight sequence is summable. By Proposition 21.1, \( \text{Lat}(S | M_n) = \{M_k : k \geq n\} \) and \( \text{Lat}(S^* | M_n^\perp) = \{M_k^\perp : k \leq n\} \). Hence if \( x \in M_n \), then the cyclic subspace \( L(x) \) belongs to \( \mathcal{H} \). Likewise, if \( y \in M_n^\perp \), then the largest \( S \) invariant subspace orthogonal to \( y \) is in \( \mathcal{H} \).

Now suppose that a unit vector \( x = \sum a_n e_n \) generates a cyclic subspace which is not in \( \mathcal{H} \). Let \( y = \sum b_n e_n \) be a unit vector orthogonal to \( L \). Then \( a_n \neq 0 \) for arbitrarily large negative \( n \) and \( b_n \neq 0 \) for arbitrarily large positive \( n \). Define
\[ \alpha_n = \begin{cases} \pi_n a_n, & n < 0 \\ \pi_n^{-1} a_n, & n \geq 0 \end{cases} \quad \text{and} \quad \beta_n = \begin{cases} \pi_n^{-1} b_n, & n < 0 \\ \pi_n b_n, & n \geq 0 \end{cases}. \]

Then for \( k \geq 0 \),

\[ 0 = (S^k x, y) = \sum_{n=-\infty}^{\infty} \left( \prod_{i=0}^{k-1} w_{n+i} \right) a_n b_{n+k} = \sum_{n=-\infty}^{\infty} \alpha_n \beta_{n+k}. \]

Let \( A_0 = 1 \) and define \( A_n > 0 \) for \( n < 0 \) so that \( \{ \log A_n, n \leq 0 \} \) is the least convex majorant of \( \{ \log |\alpha_n|, n < 0 \} \). That is, \( (n, \log A_n) \) lies on the boundary of \( \text{conv} \{ (0,0), (n, \log |\alpha_n|), n < 0 \} \). Clearly, \( |\alpha_n| \leq A_n \) for all \( n \leq 0 \). Since \( (|\alpha_n|) = o(|\alpha_n|) \) and \( \log \pi_n < -n^2 \delta \) for large \( n \), it follows that \( A_n = |\alpha_n| \) infinitely often. Similarly, let \( B_0 = 1 \) and define \( B_n > 0 \) for \( n > 0 \) so that \( \{ \log B_n, n \geq 0 \} \) is the least convex majorant of \( \{ \log |\beta_n|, n \geq 1 \} \). Again \( E = \{ n : B_n = |\beta_n| \} \) is infinite. The log convexity condition guarantees that \( B_n^{-1} B_{n+1} \) and \( A_n^{-1} A_{n-1} \) are monotone decreasing to 0 as \( n \) tends to infinity. Furthermore, the rapid growth condition implies that for infinitely many integers \( n \),

\[ B_n^{-1} B_{n+1} \leq e^{-2\gamma B_n^{-1} B_{n+1}}. \]

To see that, note that if \( B_n^{-1} B_{n+1} \geq e^{-2\gamma B_n^{-1} B_{n+1}} \) for all \( n \geq n_0 \), then

\[ B_{n+k}^{-1} B_{n+k+1} \geq e^{-2k\gamma B_n^{-1} B_{n+1}}. \]

Hence

\[ B_{n+k} \geq B_n \prod_{k=0}^{p-1} e^{-2k\gamma B_n^{-1} B_{n+1}} = e^{-\gamma \sum_{k=0}^{p-1} B_n^{-1} B_{n+1}}. \]

Taking logs yields

\[ -\log \pi_{n+p} \leq -\log B_{n+p} \leq (2-p)\gamma + (p-1)\log B_n - p \log B_{n+1}. \]

Divide by \( (n+p)^2 \) and take the limit as \( p \to \infty \), and

\[ \limsup_{n \to \infty} \frac{-\log \pi_{n+p}}{(n+p)^2} \leq \gamma. \]

This contradicts the hypotheses, so our claim is valid. Take a large integer \( n \) so that

\[ L = B_n^{-1} B_{n+1} \leq e^{-2\gamma B_n^{-1} B_{n+1}}. \]

Then choose a negative integer \( m \) so that

\[ M = A_m^{-1} A_{m-1} \leq e^{\gamma L} < A_m^{-1} A_{m+1}. \]

This implies that \( \log A_m \) changes slope at \( m \), hence \( A_m = |\alpha_m| \). Likewise, \( B_n = |\beta_n| \). Set \( p = n - m \). Then
\[ 0 = \alpha_m^{-1} \beta_n^{-1} \sum_{k=-\infty}^{\infty} \alpha_k \beta_{k+p} = \alpha_m^{-1} \beta_n^{-1} \left( \sum_{k=-p}^{0} + \sum_{k=0}^{0} + \sum_{k>0} \right) \alpha_k \beta_{k+p} . \]

These three terms, denoted \( S_1, S_2, \) and \( S_3, \) will be estimated separately.

For \( k \geq 0, \) \( |\beta_k| \leq B_k. \) When \( k = n+s \)

\[ B_{n+s} = B_n \prod_{i=0}^{s-1} B_{n+i} \leq L^s B_n, \quad s \geq 0 . \]

Similarly, if \( k = n-s, \)

\[ B_{n-s} = B_n \left( \prod_{i=1}^{s} B_{n-i} \right)^{-1} \leq e^{-2\gamma s L^{-s}} B_n, \quad 1 \leq s \leq n . \]

Likewise, for \( k \leq 0, \) \( |\alpha_k| \leq A_k; \) and

\[ A_{m-s} \leq M^s A_m \leq e^{\gamma s L^s A_m}, \quad s \geq 0 \]

and

\[ A_{m+s} \leq M^{-s} A_m \leq e^{-\gamma s L^{-s} A_m}, \quad 1 \leq s \leq |m| . \]

Hence for \(-n \leq s \leq |m|,\)

\[ A_m^{-1} B_n^{-1} A_{m+s} B_{n+s} \begin{cases} \leq e^{\gamma |s| L^s} |L|^s \leq 2 \gamma |s| L^s = e^{-\gamma |s|} |L^s| & -n \leq s \leq -1 \\ = 1 & s = 0 \\ \leq e^{-\gamma s L^{-s} L^s} = e^{-\gamma s} & 1 \leq s \leq |m| \end{cases} . \]

Consequently,

\[ |S_2| = |\alpha_m^{-1} \beta_n^{-1} \sum_{k=-p}^{0} \alpha_k \beta_{k+p}| \geq 1 - \sum_{k=-p}^{0} A_m^{-1} B_n^{-1} A_k B_{k+p} \]

\[ \geq 1 - 2 \sum_{s=1}^{\infty} e^{-\gamma s} = \frac{1 - 3 e^{-\gamma}}{1 - e^{-\gamma}} > 0 . \]

This term is bounded below independent of the choice of \( n. \) So a contradiction will be obtained if the other two terms can be made arbitrarily small for \( n \) large.

The estimates above yield as special cases:

\[ A_m^{-1} B_n^{-1} A_p B_0 \leq e^{-\gamma |n|} \quad \text{and} \quad A_m^{-1} B_n^{-1} A_0 B_p \leq e^{-\gamma |m|} . \]

Hence

\[ A_m^{-1} B_n^{-1} \leq \min \{ e^{-\gamma |n|} A_p^{-1} e^{-\gamma |m|} B_p^{-1} \} . \]

Since \( B_n^{-1} B_{n+1} \) is monotone decreasing, \( B_p^{-1} B_{p+k} \leq B_{p+k-1}. \) So,
\[ |S_\beta| = |A_n^{-1}B_n^{-1} \sum_{k \geq 0} \alpha_k \beta_{k+p}| \leq e^{-\gamma |m|} |B_p^{-1} \sum_{k \geq 0} \alpha_k|B_{k+p} \]
\[ \leq e^{-\gamma |m|} |B_1^{-1} \sum_{k \geq 0} \alpha_k|B_{k+1} . \]

It remains to show that \( \sum_{k \geq 0} |\alpha_k|B_{k+1} \leq \infty \). But \( \log \pi_k \) is a convex majorant of \( \{ \log |\beta_k| \} \) since \( w_k \) is monotone. Thus \( B_{k+1} \leq \pi_{k+1} \). Therefore,
\[ |\alpha_k|B_{k+1} \leq \pi_k^{-1}|\alpha_k|\pi_{k+1} = w_k a_k | < w_k . \]

This is summable, so \( |S_\beta| \) can be made arbitrarily small by a sufficiently large \( n \) (and hence \( |m| \)). Similarly, \( |S_1| \) can be made small. This contradicts \( S_1 + S_2 + S_3 = 0 \), and hence \( L(x) \) must belong to \( \mathcal{H} \). \( \blacksquare \)

21.B Unitary Orbits of Nest Algebras. Let \( \mathcal{H} \) be a nest. Let \( \mathcal{U}(\mathcal{H}) \) denote the norm closure of \( \{ UTU^*: T \in \mathcal{T}(\mathcal{H}), U \text{ unitary} \} \). Similarly, let
\[ \mathcal{U}_a(\mathcal{H}) = \{ UTU^* + K: T \in \mathcal{T}(\mathcal{H}), U \text{ unitary}, K \text{ compact} \} \]
\[ = \{ UTU^*: T \in \mathcal{Q} \mathcal{T}(\mathcal{H}), U \text{ unitary} \} \]
and
\[ \mathcal{U}^0(\mathcal{H}) = \{ A \in B(\mathcal{H}): \text{for all } \epsilon > 0, \text{there are } T \in \mathcal{T}(\mathcal{H}), \]
\[ U \text{ unitary, and } K \text{ compact such that } ||K|| < \epsilon \]
and \( A = UTU^* + K \} \).

Note the easy relations \( \mathcal{U}_a^0(\mathcal{H}) \subseteq \mathcal{U}(\mathcal{H}) \subseteq \overline{\mathcal{U}_a^0(\mathcal{H})} \) and \( \mathcal{U}_a(\mathcal{H}) \subseteq \mathcal{U}_a(\mathcal{H}) \). The analysis of these sets requires detailed information about the structure of operators which cannot be dealt with in this book. A good reference for this material is Herrero [2].

Recall that an operator \( A \) is quasitriangular if there is an increasing sequence \( P_n \) of finite rank projections with \( \bigvee P_n = I \) such that
\[ \lim_{n \to \infty} ||P_n A P_n^-|| = 0 \]. Let \( \mathcal{QT} \) denote the set of quasitriangular operators.

It is an easy exercise (Exercise 12.1) to show that every quasitriangular operator \( A \) can be expressed as \( A = T_\epsilon + K_\epsilon \) where \( T_\epsilon \) is triangular and \( K_\epsilon \) is compact with \( ||K_\epsilon|| < \epsilon \). Since \( \mathcal{QT} \) is norm closed, it follows from this simple observation and its converse that if \( \mathcal{H} \) is a nest of order type \( \omega + 1 \) with only finite dimensional atoms, then
\[ \mathcal{U}(\mathcal{H}) = \mathcal{U}_a(\mathcal{H}) = \mathcal{U}_a(\mathcal{H}) = \mathcal{QT} \]
Likewise, if \( \mathcal{H} \) has order type \( (\omega + 1)^* \) with finite rank atoms, then
\[ \mathcal{U}(\mathcal{H}) = \mathcal{U}_a(\mathcal{H}) = \mathcal{U}_a(\mathcal{H}) = \mathcal{QT}^* \].
Let \( \sigma_d(T) \) denote the isolated eigenvalues of \( T \) of finite multiplicity. If \( \lambda \) belongs to \( \sigma_d(T) \), let \( E_T(\lambda) \) denote the Riesz projection corresponding to the eigenspace for \( \lambda \). When \( X \) is a compact subset of the plane, let \( X^\wedge \) denote the polynomially convex hull of \( X \). The complement \( \mathcal{C}\setminus X \) has a unique unbounded component \( O_\infty \) and \( X^\wedge = \mathcal{C}\setminus O_\infty \). Thus the components of \( X^\wedge \) are always simply connected. Define

\[
B_\lambda (X^\wedge)_d = \{ T \in B (X^\wedge): \sum_{\lambda \in \sigma_d(T) \setminus \sigma_d(T)^\wedge} \text{rank } E_T(\lambda) \leq d \} .
\]

We can now state the main theorem.

21.7 Theorem. Let \( \mathcal{H} \) be a nest on a separable space.

1) If \( \mathcal{H} \) is well ordered with finite dimensional atoms, then

\[
U(\mathcal{H}) = U_0^0(\mathcal{H}) = U_0(\mathcal{H}) = QT^* .
\]

2) If \( \mathcal{H}^\perp \) is well ordered with finite dimensional atoms, then

\[
U(\mathcal{H}) = U_0^0(\mathcal{H}) = U_0(\mathcal{H}) = QT^* .
\]

3) If neither (1) nor (2) holds, let \( d = \sum_{A \in A} \dim A \), where \( A \) denotes the set of atoms of \( \mathcal{H} \). Then

3a) when \( d = \infty \) \( U(\mathcal{H}) = U_0^0(\mathcal{H}) = U_0(\mathcal{H}) = B (\mathcal{K}); \)

3b) when \( d < \infty \) \( U(\mathcal{H}) = U_0^0(\mathcal{H}) = B (\mathcal{K}^\wedge)_d \) and \( U_0(\mathcal{H}) = B (\mathcal{H}). \)

We now state without proof some results that are required. A few of the easier results will be included in the Exercises.

21.8 Lemma. Let \( T \) be a bounded operator on \( \mathcal{H}^{(a)} \) with matrix \( (T_{ij}) \). Suppose \( T \) is block upper triangular \( (T_{ij} = 0 \text{ if } j < 0 \text{)} \) and \( T_{ii} \) is quasitriangular for all \( i \geq 1 \). Then \( T \) is quasitriangular.

21.9 Theorem (Apostol, Foiaş, Voiculescu). An operator \( T \) in \( B (\mathcal{H}) \) is quasitriangular if and only if \( \{ \lambda: T - \lambda I \text{ is semi Fredholm, } \text{ind}(T - \lambda I) < 0 \} \) is empty.

21.10 Theorem (Weyl-von Neumann-Berg). Let \( N \) and \( M \) be normal operators such that \( \sigma_d(N) = \sigma_d(M) \) and \( \sigma_0(N) = \sigma_0(M) \) including multiplicity. Then \( N \cong M \).

21.11 Theorem (Voiculescu). Let \( T \) be any operator in \( B (\mathcal{H}) \). Suppose \( \rho \) is a representation of \( C^*(T) + K/K \) and \( A = \rho(T) \). Then

\[
T \cong T \oplus A^{(a)}.
\]
The following lemma is an easy step in the proof of Theorem 21.9.

**21.12 Lemma.** Let $T$ be an operator in $B(\mathcal{H})$. Given $\epsilon > 0$ and normal operators $M_1$ and $M_2$ such that $\sigma(M_1) \subseteq \sigma_{\epsilon\epsilon}(T)$ and $\sigma(M_2) \subseteq \sigma_{\epsilon\epsilon}(T)$ (the left and right essential spectra of $T$, respectively), there is a compact operator $K$ such that $\|K\| < \epsilon$ and

$$T - K \simeq \begin{bmatrix} M_1 & * & * \\ 0 & * & * \\ 0 & 0 & M_2 \end{bmatrix}.$$

(Either $M_1$ or $M_2$ may be absent.)

**21.13 Corollary.** If $\mathcal{H}$ has an infinite dimensional atom, then

$$U_{\epsilon\epsilon}(\mathcal{H}) = U(\mathcal{H}) = U_{\epsilon\epsilon}(\mathcal{H}) = B(\mathcal{H}).$$

**Proof.** Let the atom be $A = N_2 \oplus N_1$. Given $T$ in $B(\mathcal{H})$, pick a constant $\lambda$ in $\sigma_\epsilon(T)$, and set $M_1 \simeq \lambda I \mid N_1$ and $M_2 \simeq \lambda I \mid N_2$. By the previous lemma, there is a compact operator $K$ so that $\|K\| < \epsilon$, and

$$T - K \simeq \begin{bmatrix} \lambda I & * & * \\ 0 & * & * \\ 0 & 0 & \lambda I \end{bmatrix}$$

acting on $N_1 \oplus A \oplus N_2$. Clearly, this belongs to $T(\mathcal{H})$. Hence $U_{\epsilon\epsilon}(\mathcal{H}) = B(\mathcal{H})$, and the lemma follows. 

**21.14 Lemma.** If $\mathcal{H}$ has an increasing sequence of atoms, then $U_{\epsilon\epsilon}(\mathcal{H})$ contains QT.

**Proof.** It clearly suffices to show that QT is contained in $U_{\epsilon\epsilon}(\mathcal{H})$ where $\mathcal{H}$ is a larger nest containing $\mathcal{H}$. So it may be assumed that there is an increasing sequence $A_n = N_n \oplus M_n$ of one dimensional atoms. Let $T$ be a quasitriangular operator. Let $\rho$ be any representation of $C^*(T)$, and let $A = \rho(T)$. By Voiculescu’s Theorem, $T \in T \oplus A^{(\varepsilon)} \simeq T \oplus (A^{(\varepsilon)})^{(\varepsilon)}$. Now if $A - \lambda I$ is right invertible, then $T - \lambda I$ is semi Fredholm and hence has $\text{ind}(T - \lambda I) \geq 0$. Thus $(T - \lambda I)^{-}$ is left invertible in the Calkin algebra, whence $A - \lambda I$ is invertible. Thus

$$\sigma(A^{(\varepsilon)}) = \sigma(T(A^{(\varepsilon)})) = \sigma_{\epsilon\epsilon}(A^{(\varepsilon)}).$$

In particular, $\text{ind}(A^{(\varepsilon)} - \lambda I) = 0$ or $+\infty$. By Theorem 21.9, $A^{(\varepsilon)}$ is quasitriangular.

Pick $\lambda$ in $\sigma(A^{(\varepsilon)})$, which is contained in $\sigma_\epsilon(T)$. Let $N_\omega = \bigvee_{n \geq 1} N_n$.

Define normal operators $J_0 = \lambda I \mid N_\omega$ and $J_n = \lambda I \mid M_n \oplus N_{n-1}$ for $n \geq 1$. By Lemma 21.12, given $\epsilon > 0$, there are compact operators $K_n$. 

n ≥ 0 such that ∥Kₙ∥ < 2⁻ⁿ⁻¹ε such that

\[
T - K₀ ≃ \begin{bmatrix}
B₀ & * \\
0 & J₀
\end{bmatrix} \quad \text{and} \quad A^{(σ)} - Kₙ ≃ \begin{bmatrix}
Jₙ & * \\
0 & Bₙ
\end{bmatrix}.
\]

Moreover, it follows that Bₙ are quasitriangular. Hence we can assume that an additional compact perturbation has been included in Kₙ, n ≥ 0 so that Bₙ are triangular with respect to bases \{eₙ,k : k ≥ 0, n ≥ 0\}.

Let \( K = \sum_{n ≥ 0} Kₙ \). Since \( ∥K∥ < ε \), there is a compact operator \( K' \) with \( ∥K'∥ < ε \) such that

\[
T - K' ≋ T - K₀ ⊕ \sum_{n ≥ 1} A^{(σ)} - Kₙ \equiv \begin{bmatrix}
B₀ & * \\
0 & J₀
\end{bmatrix} \oplus \sum_{n ≥ 1} \begin{bmatrix}
Jₙ & * \\
0 & Bₙ
\end{bmatrix} = T₀.
\]

It remains to show that \( T₀ \) is unitarily equivalent to an operator in \( T(\mathcal{H}) \).
Let \( fₙ \) be a unit vector in the atom \( Aₙ \). Let \( U \) be a unitary such that

\[
Ueₙ,k = f_{2ₙ+2k+1} \quad n ≥ 0, k ≥ 0,
\]

\[
U(\text{dom } J₀) = N⁻, \quad U(\text{dom } Jₙ) = Mₙ \ominus N⁻_{n-1}, \quad n ≥ 1.
\]

Then \( UT₀U^* \) is scalar valued on the intervals \( Mₙ \ominus N⁻_{n-1} \) and \( N⁻ \), and is upper triangular with respect to the nest

\[
\{0 = N₀, M₁, N₁, ..., Nₙ, \mathcal{H}\}.
\]

Thus \( UT₀U^* \) belongs to \( T(\mathcal{H}) \).

\[\text{21.15 Corollary. If } \mathcal{H} \text{ is well ordered with only finite dimensional atoms, then } U(\mathcal{H}) = U₀(\mathcal{H}) = Uₙ(\mathcal{H}) = QT.\]

\[\text{Proof. By Lemma 21.14, } U₀(\mathcal{H}) \text{ contains } QT. \text{ Clearly, it suffices to show that } T(\mathcal{H}) \text{ is contained in } QT. \text{ This will be shown by induction on the ordinal type of } \mathcal{H} \text{ (always a successor ordinal } α₊1 \text{ since } \mathcal{H} \text{ is always the largest element of } \mathcal{H}). \text{ This result has already been noted for the first case } ω₊1. \text{ If } α = β₊1 \text{ and it holds for nests isomorphic to } β₊1, \text{ then every } T \text{ in } T(\mathcal{H}) \text{ has the form}
\]

\[
T = \begin{bmatrix}
T₁ & K₁ \\
0 & K₂
\end{bmatrix}
\]

where \( T₁ \) belongs to a nest order isomorphic to \( β₊1 \), and \( K₂ \) acts on a finite dimensional space. Thus \( T₁ \) is quasitriangular by the induction hypothesis. Clearly, \( T \) is also quasitriangular. So the result follows for \( α₊1 \).
The other possibility is that $\alpha$ is a limit ordinal. Since $\alpha$ is countable, there are ordinals $\alpha_k < \alpha$ such that $\alpha = \sum_{k \geq 1} \alpha_k$. So every $T$ in $T(\mathcal{N})$ where $\mathcal{N}$ has order type $\alpha + 1$ decomposes as

$$T \simeq \begin{bmatrix}
T_1 & * & * & * \\
T_2 & * & & \\
 & T_3 & * \\
0 & & & * & & \ddots
\end{bmatrix}$$

where $T_k$ belongs to $T(\mathcal{M}_k)$ where $\mathcal{M}_k$ has order type $\alpha_k + 1$. By the induction hypothesis, each $T_k$ is quasitriangular. Then Lemma 21.8 implies that $T$ is also quasitriangular. Hence the result follows for $\alpha$. The induction is complete and the corollary follows.

21.16 Corollary. If $\mathcal{N}^\perp$ is well ordered with only finite dimensional atoms, then

$$U(\mathcal{N}) = U_e(\mathcal{N}) = U_a(\mathcal{N}) = QT^*.$$

To progress further, we need more structural lemmas. These are proved using the techniques developed for Theorem 21.9. They will be stated here without proof. Caveat: Lemmas 21.17 and 21.18 are different.

21.17 Lemma. Let $T$ be an operator in $B(\mathcal{N})$ and let $\epsilon > 0$. Then there is a compact operator $K$ with $\|K\| < \epsilon$, and there are quasitriangular operators $T_1$ and $T_2$ in $B(\mathcal{N})$ so that

$$T - K \simeq \begin{bmatrix} T_1 & * \\
0 & T_2^* \end{bmatrix}.$$ 

Furthermore, it may be arranged that either $\sigma_d(T_1)$ or $\sigma_d(T_2)$ is empty.

21.18 Lemma. Let $T$ be an operator in $B(\mathcal{N})$, and let $\epsilon > 0$. Then there is a compact operator $K$ with $\|K\| < \epsilon$, and there are quasitriangular operators $T_1$ and $T_2$ in $B(\mathcal{N})$ such that

$$T - K \simeq \begin{bmatrix} T_1^* & * \\
0 & T_2 \end{bmatrix}.$$ 

Furthermore, it may be arranged that either $\sigma_d(T_1)$ or $\sigma_d(T_2)$ is empty.
21.19 Corollary. If $\mathcal{H}$ has both an increasing sequence of atoms and a decreasing sequence of atoms, then $U_0^0(\mathcal{H}) = U(\mathcal{H}) = U_0(\mathcal{H}) = B(\mathcal{H})$.

Proof. $\mathcal{H}$ must contain an element $N_0$ such that $\mathcal{H}_1 = \{N \in \mathcal{H}: N \leq N_0\}$ and $\mathcal{H}_0 = \{N \oplus N_0: N \in \mathcal{H}, N \geq N_0\}$ are infinite nests, one containing an increasing sequence of atoms and the other containing a decreasing sequence of atoms. By Lemma 21.14, one of $T(\mathcal{H}_1)$ contains $QT$ and the other contains $QT^*$. So $U_0^0(\mathcal{H})$ contains either

\[
\begin{bmatrix}
QT & * \\
0 & QT^*
\end{bmatrix}
\quad \text{or} \quad
\begin{bmatrix}
QT^* & * \\
0 & QT
\end{bmatrix}.
\]

Hence Lemma 21.17 or Lemma 21.18 implies that $U_0^0(\mathcal{H}) = B(\mathcal{H})$. $\blacksquare$

21.20 Lemma. Let $T$ be an operator in $B(\mathcal{H})$, and let $\epsilon > 0$. There is a compact operator $K$ with $\|K\| < \epsilon$, an operator $R$ such that

\[
\sigma_+(R) = \sigma_{+\epsilon}(R) = \sigma_{+\epsilon}(T) = \sigma_{+\epsilon}(R) \quad \text{and} \quad \sigma_0(R) = \sigma_0(T) \setminus \sigma_+(T),
\]

and bounded analytic functions $h_n$ in $H^\infty$ corresponding to Toeplitz operators $T_{h_n}$ on $H^2$ such that

\[
T - K \simeq \begin{bmatrix}
\sum_{n \geq 1} \oplus T_{h_n}^{(\infty)} & * & * \\
0 & R & * \\
0 & 0 & \sum_{n \geq 1} \oplus T_{h_n}^{(\infty)}
\end{bmatrix}.
\]

21.21 Lemma. Suppose that $T$ is a biquasitriangular operator ($T \in QT \cap QT^*$) such that $\sigma_0(T)$ is empty. Let $\epsilon > 0$ be given. Then there is a compact operator $K$ with $\|K\| < \epsilon$ and there are normal operators $N_j$ and block diagonal operators $D_j$, $1 \leq j \leq 4$, such that $\sigma(D_j) \subseteq \sigma(N_j) = \sigma_+ (N_j) = \sigma_\infty (T)$ and

\[
T - K \simeq \begin{bmatrix}
N_1 \oplus D_1 & * & * & * \\
0 & N_2 \oplus D_2 & * & * \\
0 & 0 & N_3 \oplus D_3 & * \\
0 & 0 & 0 & N_4 \oplus D_4
\end{bmatrix}.
\]
21.22 Lemma. Let \( D = \sum_{n \geq 1} \oplus D_n \) be a direct sum of finite rank operators, and let \( N \) be a normal operator such that \( \sigma(D) \subseteq \sigma_s(N) = \sigma(N) \). Given \( \epsilon > 0 \), there is a compact operator \( K \) with \( \|K\| < \epsilon \) such that

\[
N \oplus D - K \cong \begin{bmatrix}
\lambda_1 I & \lambda_2 I & \ast \\
\lambda_3 I & \ast & \\
0 & \ddots & \ddots
\end{bmatrix}
\]

where the matrix acts on \( \mathcal{H}^{(a)} \).

Proof. Put each \( D_n \) in triangular form with diagonal entries \( \{\lambda_{n,j} : 1 \leq j \leq j_n\} \). Then \( \sigma(D) \) contains \( \bigcup_{n \geq 1} \sigma(D_n) \), and thus so does \( \sigma(N) \).

By the Weyl-von Neumann-Berg Theorem, \( N \not\cong \sum_{n \geq 1} \oplus \lambda_{n,j} I \oplus \sum_{n \geq 1} \oplus \mu_k I \) where \( \{\mu_k, k \geq 1\} \) is a dense subset of \( \sigma(N) \). Hence

\[
N \oplus D \cong \sum_{n \geq 1} \oplus \begin{bmatrix}
\mu_n I \\
\lambda_{n,1} I & 0 \\
0 & \lambda_{n,2} I \\
0 & \lambda_{n,j_n} I
\end{bmatrix} \oplus \begin{bmatrix}
\mu_{n,1} \\
\lambda_{n,2} & \ast \\
0 & \lambda_{n,j_n}
\end{bmatrix}
\]

21.23 Corollary. Let \( \mathcal{N} \) be a continuous nest. Then \( \mathcal{U}_0^2(\mathcal{N}) \) contains \( B(\mathcal{H})_0 \). Hence \( \mathcal{U}_s(\mathcal{N}) = B(\mathcal{H}) \).

Proof. Let \( T \) be an operator in \( B(\mathcal{H}) \) such that \( \sigma_D(T) \) is contained in \( \sigma_s(T) \). Given \( \epsilon > 0 \), apply Lemma 21.20 to produce a small perturbation.
\[ T - K \simeq \begin{bmatrix} \sum_{n \geq 1} \oplus T_{h_n}^{[\infty]} & * & * \\ 0 & R & * \\ 0 & 0 & \sum_{n \geq 1} \oplus T_{h_n}^{[\infty]} \end{bmatrix}, \]

and \( \sigma(R) = \sigma_e(R) = \sigma_{te}(R) = \sigma_e(T) \). Theorem 21.9 implies that
\( R \) is biquasitriangular. Thus an application of Lemmas 21.21 and 21.22 produces a small compact perturbation \( R_0 \) of \( R \) with an upper triangular form on \( H^{[\infty]} \oplus H^{[\infty]} \oplus H^{[\infty]} \oplus H^{[\infty]} \) with scalar entries on the diagonal.

Split the continuous nest \( \mathcal{N} \) into three intervals, each of which is a continuous nest \( \mathcal{N}_i \), \( 1 \leq i \leq 3 \). The nest \( \mathcal{N}_L \) can be decomposed into intervals order equivalent to \( \omega + \omega + \omega + \omega \). Let \( U_2 \) be a unitary carrying \( H^{[\infty]} \oplus H^{[\infty]} \oplus H^{[\infty]} \oplus H^{[\infty]} \) onto the domain of \( \mathcal{N}_2 \) matching each copy of \( H \) to the corresponding interval. Then since the diagonal entries of \( R_0 \) are scalar, \( U_2 R_0 U_2^* \) belongs to \( \mathcal{T}(\mathcal{N}_2) \).

Let \( S^{[\infty]} \) denote the unilateral shift of infinite multiplicity. Let \( \mathcal{M} \) be any continuous nest, and partition \( \mathcal{M} \) into intervals \( \{ E_k, k \geq 1 \} \) with \( E_{k+1} \ll E_k \). Then \( S^{[\infty]} \) is unitarily equivalent to any strictly upper triangular isometry that carries each \( E_k \) onto \( E_{k+1} \). So \( S^{[\infty]} \) belongs to \( \mathcal{T}(\mathcal{M}_0) \) where \( \mathcal{M}_0 \) is unitarily equivalent to \( \mathcal{M} \). Hence so does every operator in the WOT closed algebra generated by \( S^{[\infty]} \), which includes \( T_{h}^{[\infty]} \) for every \( h \) in \( H^{[\infty]} \). Now split \( \mathcal{N}_2 \) into countably many intervals \( F_n \). By the above remarks, an operator unitarily equivalent to \( T_{h}^{[\infty]} \) belongs to \( \mathcal{T}(F_n \mathcal{N}_1) \). Hence \( \sum_{n \geq 1} \oplus T_{h}^{[\infty]} \) is unitarily equivalent to an operator in \( \mathcal{T}(\mathcal{N}_1) \).

Since \( \mathcal{T}(\mathcal{N}_L)^* = \mathcal{T}(\mathcal{N}_L)^\perp \) is also a continuous nest algebra, \( \sum_{n \geq 1} \oplus T_{h}^{[\infty]} \) is unitarily equivalent to an operator in \( \mathcal{T}(\mathcal{N}_L) \). Putting all the pieces together demonstrates that \( T \) belongs to \( U_{a}(\mathcal{N}) \).

Every operator \( T \) has a compact perturbation with no isolated eigenvalues of finite multiplicity. Hence \( U_{a}(\mathcal{N}) = B(\mathcal{N}) \).

**Corollary.** Let \( \mathcal{N} \) be a nest such that neither \( \mathcal{N} \) nor \( \mathcal{N}^\perp \) is well ordered. Then \( U_{a}(\mathcal{N}) \) contains \( B(\mathcal{N}) \) and hence \( U_{a}(\mathcal{N}) = B(\mathcal{N}) \). If the span of the atoms is infinite dimensional, then \( U_{a}(\mathcal{N}) = u(\mathcal{N}) = U_{a}(\mathcal{N}) = B(\mathcal{N}) \).

**Proof.** First assume \( d = \infty \). If \( \mathcal{N} \) has an infinite dimensional atom, apply Corollary 21.13. If \( \mathcal{N} \) has both an increasing sequence of atoms and a decreasing sequence of atoms, apply Corollary 21.19. Otherwise, the atoms of \( \mathcal{N} \) are either well ordered or those of \( \mathcal{N}^\perp \) are. Assume the former. Since \( \mathcal{N} \) is not well ordered, it must have a continuous part. As the atomic part is well ordered, \( \mathcal{N} \) contains an interval \( E_2 \) on which \( \mathcal{N} \) is continuous.
This splits \( \mathcal{N} \) into intervals \( E_1, E_2, E_3 \). One of \( E_1 \) or \( E_2 \) contains an increasing sequence of atoms. For definiteness, say \( E_3 \) has this property.

By Lemma 21.18, for every operator \( T \in \mathcal{B}(\mathcal{N}) \) and \( \epsilon > 0 \), there is a compact operator \( K_1 \) with \( \| K_1 \| < \epsilon \) such that

\[
T - K_1 \simeq \begin{bmatrix}
T_1^* \\
0 & T_2
\end{bmatrix}
\]

where \( T_2 \) is quasitriangular and \( \sigma_0(T_1^*) \) is empty. Let \( \lambda \) be any point in \( \sigma_e(T_1^*) \), and let \( M_1 = \lambda I \mid E_1 \). By Lemma 21.12, a second small compact perturbation yields

\[
T - K_1 - K_2 \simeq \begin{bmatrix}
M_1 & * & * \\
0 & B & * \\
0 & 0 & T_2
\end{bmatrix}
\]

where \( \sigma_0(B) = \sigma_0(T_1^*) \) is empty. By Corollary 21.15, \( T_2 \) belongs to \( \mathcal{U}_0^0(\mathcal{N}E_3) \). By Corollary 21.23, \( B \) belongs to \( \mathcal{U}_0^0(\mathcal{N}E_2) \). Clearly, \( M_1 \) belongs to \( \mathcal{T}(\mathcal{N}E_1) \). Hence \( T \) belongs to \( \mathcal{U}_0^0(\mathcal{N}) \); and \( \mathcal{U}_0^0(\mathcal{N}) = B(\mathcal{N}) \).

If \( d < \infty \) (i.e. \( \mathcal{N} \) has finitely many, finite rank atoms), then \( \mathcal{N} \) has an interval \( E_2 \) on which \( \mathcal{N} \) is continuous. As in the proof of Corollary 21.13, every operator \( T \) has a small compact perturbation of the form

\[
T - K \simeq \begin{bmatrix}
\lambda I & * & * \\
0 & T_0 & * \\
0 & 0 & \lambda I
\end{bmatrix}
\]

If \( \sigma_0(T) \setminus \sigma_e(T) \) is empty, the same follows for \( T_0 \). Then by Corollary 21.23, \( T_0 \) belongs to \( \mathcal{U}_0^0(\mathcal{N}E_2) \) and hence \( T \) belongs to \( \mathcal{U}_0^0(\mathcal{N}) \). Hence \( \mathcal{U}_0^0(\mathcal{N}) \) contains \( B(\mathcal{N})_0 \) and \( \mathcal{U}_0^0(\mathcal{N}) = B(\mathcal{N})_d \).

The full Theorem 21.7 has been proven except for the following:

\[21.25 \ \text{Lemma.} \ \text{Let} \ \mathcal{N} \ \text{be a nest with finitely many finite atoms of total dimension} \ d. \ \text{Then} \ \mathcal{U}_0^0(\mathcal{N}) = \mathcal{U}(\mathcal{N}) = B(\mathcal{N})_d.\]

\[\text{Proof.} \ \text{Let} \ T \ \text{belong to} \ B(\mathcal{N}), \ \text{and let} \]

\[
p = \sum_{\lambda \in \sigma_0(T) \setminus \sigma_e(T)^\wedge} \text{rank} \ E_T(\lambda).
\]

If \( p > d \), there is a finite subset \( S = \{ \lambda_1, \ldots, \lambda_n \} \) of \( \sigma_0(T) \setminus \sigma_e(T)^\wedge \) with rank \( E_T(S) > d \). The characteristic function of \( \{ \lambda_1, \ldots, \lambda_n \} \) can be approximated uniformly in a neighbourhood of \( \sigma(T) \) by polynomials (Runge's Theorem). Hence \( E_T(S) \) belongs to the WOT closed algebra generated by \( T \). Consequently, if \( T \) belongs to \( \mathcal{T}(\mathcal{N}) \), so does \( E_T(S) \). By Ringrose's Theorem 3.4,
the atoms of $\mathcal{N}$ have total dimension at least rank $E_T(S)$, contrary to fact. Moreover, $B (\mathcal{N})_d$ is closed because every operator sufficiently close to $T$ will have isolated eigenvalues near $S$ of the same dimension. Hence $U_0^0(\mathcal{N})$ is contained in $B (\mathcal{N})_d$, as is $U(\mathcal{N})$ since it is contained in $U_0^0(\mathcal{N})$.

On the other hand, suppose $p \leq d$. Then there is an invertible operator $S$ so that

$$STS^{-1} \simeq A \oplus T_0$$

where $A$ acts on $\mathbb{C}^p$ and $T_0$ belongs to $B (\mathcal{N})_d$. Clearly, $T$ belongs to $U_0^0(\mathcal{N})$ if and only if $STS^{-1}$ belongs to $U_0^0(S \mathcal{N})$. But $S \mathcal{N}$ has precisely the same atoms, so we may assume that $T = A \oplus T_0$. Since $A$ can be put in triangular form, $A$ is unitarily equivalent to an operator $B$ in $T (\mathcal{N})$ where $B = P(E)BP(E)$ and $E$ is the sum of all the atoms of $\mathcal{N}$. Since $\mathcal{NP}(E)^\perp$ is a continuous nest, Corollary 21.23 shows that $T_0$ belongs to $U_0^0(\mathcal{N})$. Hence $T$ belongs to $U_0^0(\mathcal{N})$ as desired.

**Notes and Remarks.**

Proposition 21.2 was proven for $\omega_n = 2^{-n}$ by Donoghue [1], and in this generality by Nikol’skii [1]. Nikol’skii also showed that the monotonocity is essential. Yakubovic [1] showed that $w_n$ monotone decreasing to 0 is sufficient for unicellularity. Harrison and Longstaff [1] constructed a unicellular operator with lattice $\omega+\omega+1$. Corollary 21.6 is in Barria [1]. Theorem 21.3 is taken from Barria and Davidson [1]. They prove $\omega+1+\beta^*$ is an attainable lattice for all countable ordinals $\alpha$ and $\beta$. Theorem 21.7 is due to Domar [1]. He also shows that bilateral weighted shifts are not unicellular if

$$\liminf_{|x| \to \infty} \frac{|\log \pi_n|}{|n| + \log |n|} > -\infty.$$ 

Other nests which are attainable are constructed in Barria [2] and Rosenthal [1].

Theorem 21.7 is due to Herrero [3] and [4] and answers a question raised by Arveson in 1981. The reader should consult these papers for proofs of Lemmas 21.17, 21.18 and 21.20 which are omitted in our text. The other omitted material can be found in Herrero’s monograph [2], or in its original sources. Lemma 21.8 is due to Douglas and Pearcy [1]. (See Exercise 21.4). Theorem 21.9 appears in a long series of papers by Apostol, Fois and Voiculescu [1]. The Weyl-von Neumann-Berg Theorem was first proved by Berg [2]. (See Exercises 7.1 and 7.2). Theorem 21.11 is due to Voiculescu [2], and is related to the proof of Andersen’s Theorem presented in Chapter 12. Lemma 21.21 is contained in Voiculescu [1].
Exercises.

21.1 Suppose that \(|A_i^x| = O((n!)^{-\varepsilon})\) for \(i = 1, 2\), and let

\[
T = \begin{bmatrix} A_1 & C \\ 0 & A_2 \end{bmatrix}.
\]

Use Stirling’s formula to show that \(|T^n| = O((n!)^{-\langle \varepsilon - 1 \rangle})\) for all \(\varepsilon > 0\).

21.2 Construct a unicellular operator with lattice isomorphic to \(\omega + (\omega + 1)^* + \omega + 1 + \omega^*\). Hint: Apply Theorems 21.3 and 21.7.

21.3* Is the canonical nest on \(\ell^2(\mathbb{Q})\) attainable?

21.4 (a) Let

\[
T = \begin{bmatrix} T_{11} & T_{12} \\ 0 & T_{22} \end{bmatrix}
\]

act on \(\mathcal{H} \oplus \mathcal{H}\), and suppose \(T_{11}\) and \(T_{22}\) are in \(QT\). Prove that \(T\) is quasitriangular. Hint: Suppose that \(T_{ii}\) are triangular with respect to \(\{P_n\}\) and \(\{Q_n\}\) respectively. Show that given \(\varepsilon > 0\), there are integers \(n_k\) so that \(\sum_{k \geq 1} \|P_{n_k} T_{12} Q_k\| < \varepsilon\).

(b) Prove Lemma 21.10.

21.5 (a) Suppose \(T\) is semi Fredholm of negative index which is bounded below by one on \((\ker T)^\perp\). Let \(M\) be a finite dimensional subspace of \((\text{Ran} T)^\perp\) such that \(\dim M > \text{null}(T)\). Show that if \(N\) is any subspace containing \(M \vee (\ker T)\), then \(\|P(N)^\perp TP(N)\| \geq 1\).

(b) Show that if \(T\) is quasitriangular, then whenever \(T - \lambda I\) is semi Fredholm, \(\text{ind}(T - \lambda I) \geq 0\).

22. Commutative Subspace Lattices

In this chapter, we will examine the class of reflexive algebras with commutative subspace lattice, meaning a complete lattice of subspaces $L$ such that $\{P(L) : L \in L\}$ is abelian. This includes all nest algebras, and some of the results of this chapter are not much easier in the nest case. It will be shown that $L$ is reflexive (Theorem 22.9) and that there is a smallest weak* closed subalgebra of $\text{Alg} L$ containing a maximal abelian von Neumann algebra, denoted $A_{\text{min}}$, with the property that $\text{Lat} A_{\text{min}} = L$ (Theorem 22.16). In the case of a nest and in many other cases, one has $A_{\text{min}} = \text{Alg} L$ (22.19-22.25). This generalizes some of the results of Chapter 15.

22.1 Example. Let $(X, m)$ be a compact metric space with a finite regular Borel measure $m$. Let a pre-order $\leq$ given by a countable family $\{f_n\}$ of continuous real valued functions by the rule $x \leq y$ if $f_n(x) \leq f_n(y)$ for all $n$. This may fail to be a partial order since $x \leq y$ and $y \leq x$ may not imply $x = y$. Such a pre-order will be called a standard pre-order.

A Borel subset $E$ of $X$ is increasing if $x \in E$ and $x \leq y$ implies $y \in E$. Let $L(X, \leq, m)$ denote the set of subspaces of $L^2(X, m)$ of functions supported on increasing sets. This is in fact a complete lattice. For if $A$ and $B$ are increasing sets, so are $A \cap B$ and $A \cup B$. Let the subspace corresponding to $A$ be denoted by $L_A$ and $P(L_A) = P_A$. Then $L_A \vee L_B = L_{A \cup B}$ and $L_A \wedge L_B = L_{A \cap B}$. If $\{A_\lambda : \lambda \in \Lambda\}$ is a collection of increasing sets, let $s$ be the supremum of $m(\bigcup A_\lambda)$ as $F$ ranges over finite subsets of $\Lambda$. One can choose a countable subset $\{A_n\}$ such that $A = \bigcup_{n=1}^{\infty} A_n$ has measure $s$. Clearly, $A$ is increasing. It will be shown that $L_A = \bigvee_{\lambda \in \Lambda} L_{A_\lambda}$. Denote the closed span of $\{L_{A_\lambda} : \lambda \in \Lambda\}$ by $M$. Since $M$ contains $L_{A_n}$ for each $A_n$, $M$ contains $L_A = \bigvee_{n \geq 1} L_{A_n}$. On the other hand, suppose that for some $\lambda$, $L_{A_\lambda}$ is not contained in $L_A$. Then $m(A \cup A_\lambda) > s$ which contradicts the definition of $s$. So $M = L_A$. Similarly, $L(X, \leq, m)$ is closed under arbitrary intersections.
22.2 Lemma. \( L(X, \leq, m) \) is closed in the strong operator topology.

Proof. The space \( L^q(X, m) \) is separable, and hence the strong operator topology is metrizable. The set of projections is strongly closed, as is \( L^\infty(X, m) \). So if \( A_n \) are increasing sets, and \( P_{A_n} \) converges strongly to \( P \), then \( P = P_A \) for some Borel set \( A \). Let \( 1 \) denote the constant function. Then

\[
0 = \lim_{n \to \infty} \| P_A - P_{A_n} \|_2 = \lim_{n \to \infty} m(A \Delta A_n)
\]

(where \( A \Delta B \) denotes the symmetric difference \( (A \setminus B) \cup (B \setminus A) \).) Drop to a subsequence so that \( m(A \Delta A_n) \leq 2^{-n} \). Let \( B = \bigcap_{n=1}^{\infty} \bigcup_{k \geq n} A_k \). This is an increasing set. Moreover,

\[
m(A \setminus \bigcup_{k \geq n} A_k) \leq \lim_{k \to \infty} 2^{-k} = 0
\]

for all \( n \), so \( P_B \geq P \). Also

\[
m\left( \bigcup_{k \geq n} A_k \setminus A \right) \leq \sum_{k \geq n} 2^{-k} = 2^{-n}.
\]

Thus \( m(B \setminus A) = 0 \) and \( P_B \leq P \). So \( P = P_B \) belongs to \( L(X, \leq, m) \). \( \blacksquare \)

It is always possible to find a countable family \( \{E_n, n \geq 1\} \) of closed increasing sets so that

\[
x \leq y \text{ if and only if } \{n : x \in E_n\} \subseteq \{n : y \in E_n\}.
\]

For example, let \( r_k \) be an enumeration of the rationals and let

\[
E_{n, k} = \{x : f_n(x) \geq r_k\}.
\]

On the other hand, if \( E_n \) is such a collection, then the complete lattice generated by \( \{E_n, n \geq 1\} \) is all of \( L(X, \leq, m) \). At this point, we prove this only in a special case.

Let \( X = 2^N \) be the space of sequences \( (x_k) \) of zeros and ones with the product topology. The sets \( F_n = \{x = (x_k) : x_n = 1\} \) are closed and open, and \( \{F_{\neq n}, n \geq 1\} \) is a sub-base for this topology. The "even preorder" is given by

\[
x \leq y \iff \{n \in N : x_n \in F_{2n}\} \subseteq \{n \in N : y_n \in F_{2n}\}
\]

\[
\iff x_{2n} \leq y_{2n}, \quad n \geq 1.
\]
22.3 Lemma. Let \((X, \leq)\) be \(2^X\) with the even pre-order, and let \(\mu\) be a regular Borel measure on \(X\). Then the complete lattice generated by \(\{P_{2^n} : n \in \mathbb{N}\}\) is precisely \(L(X, \leq, \mu)\).

Proof. Let \(C^+\) be the smallest increasing set containing a set \(C\). It will be shown that \(C^+\) is closed if \(C\) is closed. The graph of the pre-order,

\[ G = \{(x,y) \in X^2 : y \leq x\} \]

is closed because \(X^2 \setminus G = \bigcup_{n \geq 1} F_{2^n} \times F_{2^n}\) is open. Let \(\pi_1\) and \(\pi_2\) be the two coordinate projections. Then

\[ C^+ = \pi_1(\pi_2^{-1}(C) \cap G) \]

is the continuous image of a compact set, and hence is closed.

Now let \(P\) be a projection in \(L(X, \leq, \mu)\), and let \(A\) be an increasing Borel set such that \(P = P_A\). By the regularity of \(\mu\), there is an increasing sequence of closed sets \(C^n_k\) contained in \(A\) such that \(\mu(A \setminus \bigcup_{n \geq 1} C^n_k) = 0\). Hence \(C^+_n\) is an increasing sequence of closed increasing sets contained in \(A\) such that \(\bigvee_{n \geq 1} P_{C^n_k} = P_A\). So it suffices to prove that \(P_C\) belongs to the lattice generated by \(\{P_{F_{2^n}} : n \in \mathbb{N}\}\) for every closed increasing set \(C\).

Let \(F^{[1]}_n = F_n, F^{(-1)}_n = F_n^c, \) and \(F^{(0)}_n = X\). For each finite sequence \(\varepsilon = \{\varepsilon_n, 1 \leq n \leq 2N\}\) of \(\pm 1\)'s, let

\[ F_{\varepsilon} = \bigcap_{n=1}^{2N} F_{n}^{(\varepsilon_n)} \]

These sets form a base for the topology. Since \(C\) is closed, \(X \setminus C\) is the union of \(E = \{F_{\varepsilon} : F_{\varepsilon} \subseteq X \setminus C\}\). Since \(C\) is increasing, it follows that if \(F_{\varepsilon}\) is disjoint from \(C\), then the decreasing set

\[ F^-_{\varepsilon} = \{x \in X : x_{2n} \leq (\varepsilon_{2n} + 1)/2, 1 \leq n \leq N\} \]

is also disjoint from \(C\). Now, \(X \setminus F^-_{\varepsilon} = \bigcup \{F_{2^n} : \varepsilon_{2n} = -1\}\). So

\[ C = \bigcap_{\varepsilon} (X \setminus F^-_{\varepsilon}) \]

belongs to the complete lattice generated by \(\{F_{2^n} : n \geq 1\}\). \(\square\)

22.4 Theorem. Let \(L\) be a commutative subspace lattice on a separable Hilbert space. Then \(L\) is unitarily equivalent to some \(L(X, \leq, m)\) of Example 22.1 where \(X\) is a compact metric space, \(m\) is a regular Borel measure on \(X\), and \(\leq\) is a standard pre-order.

Proof. Let \(L''\) denote the abelian von Neumann algebra generated by \(\{P_L : L \in L\}\). Let \(M\) be any maximal abelian von Neumann algebra containing \(L''\). Since \(B(M)\) is separable and metrizable in the strong operator
topology, one can choose countable families of projections \( \{P_n, n \geq 1\} \) and \( \{Q_n, n \geq 1\} \) which are strongly dense in \( \{P(L), L \in L\} \) and \( \text{Proj}(\mathcal{M}) \) respectively. Let

\[
A = \sum_{n=1}^{\infty} 3.9^{-n} P_n + 9^{-n} Q_n .
\]

Since each \( P_n \) and \( Q_n \) can be recovered from the spectral projections of \( A \), it follows that \( C^*(A) = C^*(P_n, Q_n, n \geq 1) \) and \( W^*(A) = \mathcal{M} \). Let \( X \) be the spectrum of \( A \). By Theorem 7.8, there is a finite regular Borel measure \( m \) on \( X \) such that \( \mathcal{M} \) is unitarily equivalent to \( L^\infty(X, m) \) acting on \( L^2(X, m) \) by multiplication, and \( A \) corresponds to \( M_2 \).

The projections \( P_n \) and \( Q_n \) correspond to multiplication by the characteristic functions of closed and open sets, which we denote \( E_{2n} \) and \( E_{2n-1} \) respectively. Since \( \{P_n, Q_n\} \) generate \( C^*(A) \), the functions \( \{x_{E_n}, n \geq 1\} \) separate the points of \( X \). Define a pre-order \( \leq \) by

\[
x \leq y \quad \text{if} \quad \{n : x \in E_{2n}\} \subseteq \{n : y \in E_{2n}\} .
\]

Then each set \( E_{2n} \) in an increasing set. The unitary equivalence carries \( L \) onto the strongly closed lattice generated by \( \{P_{E_{2n}}, n \geq 1\} \). This will be shown to be all of \( L(X, \leq, m) \).

Define a map \( \Phi \) from \( X \) onto \( Y = 2^\kappa_0 \) by \( \Phi(x)(n) = 1 \) if and only if \( x \in E_n \). Clearly, \( \Phi^{-1}(F_n) = E_n \) and \( \Phi^{-1}(F_n^c) = E_n^c \). As these sets are a sub-base for the topology of \( Y \), \( \Phi \) is continuous. Since \( \{E_n\} \) separate points, \( \Phi \) is a homeomorphism onto its image \( \Phi(X) \). The order on \( \Phi(X) \) induced from \( X \) is precisely the restriction of the even pre-order to \( \Phi(X) \). Let \( \mu \) be the regular Borel measure on \( Y \) given by

\[
\mu(A) = m(\Phi^{-1}(A \cap \Phi(X))) .
\]

There is a natural unitary equivalence of \( L^2(X, m) \) and \( L^2(Y, \mu) \). Let \( C \) be an increasing set in \( X \), and let \( D = \Phi(C) \). Let \( D^+ \) be the smallest increasing set in \( Y \) containing \( D \), namely \( \{y \in Y : \exists z \in D, y \geq z\} \). Since \( D \) is increasing in the relative order on \( \Phi(X) \), it follows that \( D = D^+ \cap \Phi(X) \). On the other hand, if \( A \) is an increasing set in \( Y \), then \( \Phi^{-1}(A \cap \Phi(C)) \) is an increasing set in \( X \). This establishes a unitary equivalence between \( \{P_C : C \in L(X, \leq, m)\} \) and \( \{P_A : A \in L(Y, \leq, \mu)\} \). This unitary equivalence takes \( \{P_{E_{2n}}, n \geq 1\} \) onto \( \{P_{E_{2n}}, n \geq 1\} \). By Lemma 22.3, \( \{P_{E_{2n}}, n \geq 1\} \) generate \( L(Y, \leq, \mu) \) as a complete lattice. Hence \( \{P_{E_{2n}}, n \geq 1\} \) generate \( L(X, \leq, m) \) as a complete lattice.

\[\square\]

Contained in this proof is the fact that if \( \{E_{2n}, n \geq 1\} \) is a collection of increasing sets which determine the order on \( (X, \leq) \), then \( \{P_{E_{2n}}, n \geq 1\} \) generates \( L(X, \leq, m) \) as a complete lattice. Just insert \( P_{E_{2n}} \) for \( P_n \) in the proof above. The proof establishes a unitary equivalence between the
complete lattice generated by \( \{P_E, n \geq 1\} \) and \( L(\leq, \mu) \), and hence with \( L(X, \leq, m) \).

Unlike the nest algebra case, there is no longer an abundance of rank one operators in \( \text{Alg} L \) to prove reflexivity. A substitute is needed. Let \( \mu \) be a finite positive regular Borel measure on \( X^2 \). The marginal measures are the measures on \( X \) given by

\[
\mu_i(A) = \mu(A \times X) \quad \text{and} \quad \mu_2(A) = \mu(X \times A). 
\]

Let \( \mathbb{A}(X,m) \) denote the linear space of signed regular Borel measures \( \mu \) on \( X^2 \) such that \( |\mu|_i \) and \( |\mu|_2 \) are absolutely continuous with respect to \( m \) and

\[
\|\mu\| = \max_{i=1,2} \left\| \frac{d|\mu|_i}{dm} \right\|_\infty < \infty.
\]

If \( \leq \) is a standard pre-order on \( X \), let \( G(\leq) = \{x, y \in X^2 : y \leq x\} \) be the graph of the pre-order. We construct certain "pseudo integral" operators in \( \text{Alg} L \).

22.5 **Theorem.** Let \( \mu \) belong to \( \mathbb{A}(X,m) \). Then there is a unique operator \( T_\mu \) acting on \( L^2(X,m) \) such that

\[
(T_\mu f, g) = \int \int_{X^2} f(y) g(x) \mu(dx) \mu(dy)
\]

for all \( f, g \) in \( L^2(X,m) \). Moreover, \( \|T_\mu\| \leq \|\mu\| \). The operator \( T_\mu \) belongs to \( \text{Alg} L(X, \leq, m) \) if and only if \( \text{supp}\mu \subseteq G = \{(x,y) \in X^2 : y \leq x\} \).

**Proof.** Define a bilinear form on \( L^2(X,m) \) by

\[
<f, g> = \int \int_{X^2} f(y) g(x) \mu(dx) \mu(dy).
\]

Then by the Cauchy-Schwartz inequality,

\[
|<f, g>| \leq \int \int_{X^2} |f(y)| |g(x)| d|\mu| \leq (\int \int_{X^2} |f(y)|^2 d|\mu|)^{1/2} (\int \int_{X^2} |g(x)|^2 d|\mu|)^{1/2}
\]

\[
= (\int_X |f(y)|^2 d|\mu|_1)^{1/2} (\int_X |g(x)|^2 d|\mu|_1)^{1/2} \leq \|f\| \|g\| \|\mu\|.
\]

Thus there is a bounded operator \( T_\mu \) with \( \|T_\mu\| \leq \|\mu\| \) such that

\[
(T_\mu f, g) = <f, g> \text{ for all } f, g \text{ in } L^2(X,m).
\]

Suppose that \( \text{supp} \mu \) is contained in \( G \). Let \( E \) be an increasing set, let \( f, g \) belong to \( L^2(X,m) \) so that \( f = \chi_E f \) and \( g = \chi_{E^c} g \). Then \( f(y)g(x) \) is supported on \( E^c \times E \) which is disjoint from \( G \). Hence \( E^c \times E \cap G \) is empty, so
\[(T_\mu f, g) = \int \int_{E^c \times E \cap G} f(y)g(x) d\mu = 0.\]

So \(T_\mu\) belongs to \(\text{Alg} L(X, \leq, m)\).

Conversely, suppose that \(T_\mu\) belongs to \(\text{Alg} L(X, \leq, m)\). For every increasing set \(E\), \(f = \chi_E f\), and \(g = \chi_E g\) in \(L^2\), one has
\[
0 = (T_\mu f, g) = \int \int_{E^c \times E} f(y)g(x) d\mu.
\]

Hence \(|\mu|(E^c \times E) = 0\). There are countably many increasing sets \(E_n, n \geq 1\) with the property that \(x \geq y\) if and only if \(y \in E_n\) implies \(x \in E_n\) for all \(n \geq 1\). Reformulating this, one obtains
\[
X^\alpha \setminus G = \bigcup_{n \geq 1} E_n^c \times E_n.
\]

Hence \(|\mu(X^\alpha \setminus G) = 0|\), whence \(\text{supp} \mu\) is contained in the closed set \(G\).

It can be shown that there is a convolution type multiplication on \(A(X, m)\) so that \(T_\mu T_\nu = T_{\mu \times \nu}\). Thus \(\{T_\mu : \mu \in A(X, m)\}\) is an algebra. We will not require this fact at this stage. The proof will be delayed until Appendix 22.31.

In order to prove reflexivity, we will show that \(A(X, m)\) is rich. A Borel subset \(K\) of \(X^2\) will be called marginally null if there are sets \(N\) and \(M\) with \(m(N) = m(M) = 0\) such that \(K\) is contained in \(N \times X \cup X \times M\). Such sets obviously cannot support a non-zero measure in \(A(X, m)\). We require the converse.

22.6 Lemma. Let \(S\) be a subspace of \(C_R(X)\) containing the constants. Let \(\phi\) be a linear functional on \(S\) such that \(1 = \phi(S) = \|\phi\|\) and let \(M_\phi\) denote the set of Hahn-Banach extensions of \(\phi\) to \(C_R(X)\). The for every \(u \in C_R(X)\),
\[
\sup \{\sigma(u) : \sigma \in M_\phi\} = \inf \{\phi(f) : f \geq u, f \in S\}.
\]

Proof. Let \(\alpha\) denote the right hand side. For any \(\sigma\) in \(M_\phi\) and \(f\) in \(S\) with \(f \geq u\),
\[
\sigma(u) \leq \sigma(f) = \phi(f).
\]

Hence the left hand side is dominated by \(\alpha\). On the other hand, one can define \(\phi_0\) on \(S+Ru\) by \(\phi_0(f+ru) = \phi(f)+r\alpha\). Suppose \(\|f+ru\| \leq 1\) and \(r \geq 0\). Then \(f+ru \leq 1\), whence \(u \leq r^{-1}(1-f)\). So
\[
\alpha \leq r^{-1}(1-\phi(f)) \quad \text{or} \quad \phi(f+ru) = \phi(f)+r\alpha \leq 1.
\]

On the other hand, if \(\sigma\) is any element in \(M_\phi\)
\[
-1 \leq \sigma(f+ru) = \phi(f)+r\sigma(u) \leq \phi(f)+r\alpha = \phi_0(f+ru).
\]

So \(\|\phi_0\| \leq 1\). By the Hahn-Banach Theorem, \(\phi_0\) has a norm one extension \(\sigma_0\) on \(C_R(X)\) and \(\sigma_0(u) = \alpha\).
Each $\sigma$ in $\mathcal{M}_\Phi$ is given by a measure $\sigma(f) = \int fd\sigma$. Thus it extends to all bounded Borel functions on $X$.

22.7 Corollary. Let $S$ and $\Phi$ be as in Lemma 22.6, and let $K$ be a compact subset of $X$. Then
\[
\sup\{\int_K d\sigma : \sigma \in M_\Phi\} = \inf\{\Phi(f) : f \in S, f \geq \chi_K\}.
\]

Proof. As before, the right hand side is the larger of the two terms. Let the left hand side be $\delta$, and fix $\epsilon > \delta$. Then since $\Phi(1) = 1,$
\[
\int_{X\setminus K} d\sigma \geq 1-\delta > 1-\epsilon
\]
for every $\sigma$ in $M_\Phi$. By the regularity of $\sigma$, there is a compact subset $C$ of $X \setminus K$ with $\sigma(C) > 1-\epsilon$. By Urysohn's lemma, there is a continuous real valued function $u_\sigma$ with $\chi_C \leq u_\sigma \leq \chi_{X\setminus K}$. Thus $\sigma(u_\sigma) > 1-\epsilon$. Let $O_\sigma = \{\sigma' \in M_\Phi : \sigma'(u_\sigma) > 1-\epsilon\}$. The collection $\{O_\sigma : \sigma \in M_\Phi\}$ is an open cover of the weak* compact set $M_\Phi$. Let $O_{\sigma_1}, \ldots, O_{\sigma_n}$ be a finite subcover, and let
\[
u = \max\{u_{\sigma_1}, \ldots, u_{\sigma_n}\}.
\]
Then $u \leq \chi_{X\setminus K}$ and $\sigma(u) > 1-\epsilon$ for all $\sigma$ in $M_\Phi$. By Lemma 22.7,
\[
\inf\{\Phi(f) : f \in S, f \geq \chi_K\} \leq \inf\{\Phi(f) : f \in S, f \geq 1-u\}
= \sup\{\sigma(1-u) : \sigma \in M_\Phi\} < \epsilon.
\]
As $\epsilon > \delta$ is arbitrary, the nontrivial half of the inequality follows. ■

22.8 Theorem. Let $K$ be a compact subset of $X^2$ which is not marginally null. Then there is a non-zero measure $\mu$ in $A(X;m)$ with supp$(\mu)$ contained in $K$.

Proof. Let $S = \{h \in C_\Phi(X^2) : h(x,y) = f(x)+g(y), f, g \in C_\Phi(X)\}$. Let $\phi(h) = \int h dm^2$. The set $M_\Phi$ is precisely the set of positive measures such that $|\mu|_1 = |\mu|_2 = m$. It suffices to show that
\[
\sup\{\int_K d\sigma : \sigma \in M_\Phi\} > 0.
\]
For then, one takes $\sigma$ in $M_\Phi$ with $\int_K d\sigma > 0$ and sets $\mu(A) = \sigma(A \cap K)$ to obtain the desired measure.

Otherwise, one applies Corollary 22.7 to obtain a sequence $h_n$ in $S$ with $h_n \geq \chi_K$ and $\phi(h_n) < 2^{-n}$. Decompose $h_n(x,y) = f_n(x)+g_n(y)$. Make this decomposition unique by stipulating that $\min f_n(x) = 0$. Choose $x_0$ with $f_n(x_0) = 0$, and note that $g_n(y) = h_n(x_0,y) \geq 0$ for all $y$. Then
\[ 2^{-n} > \phi(h_n) = \int \| f_n \| \| g_n \| \, dm. \]

Let \( A_n = \{ x \in X : \| f_n(x) \| + |g_n(x)| \geq \frac{1}{2^n} \} \) and \( B_n = \bigcup_{k \geq n} A_k. \) Then \( m(A_k) < 2^{1-k} \), whence \( m(B_n) < 2^{2-n} \); and

\[ K \subseteq (A_n \times X) \cup (X \times A_n) \subseteq (B_n \times X) \cup (X \times B_n). \]

Hence if \( B = \bigcap_{n \geq 1} B_n \), one has \( m(B) = 0 \) and

\[ K \subseteq \bigcap_{n \geq 1} (B_n \times X) \cup (X \times B_n) = (B \times X) \cup (X \times B). \]

Consequently, \( K \) is marginally null, contrary to hypothesis. 

The set \( \{ T_\mu : \mu \in \mathcal{A}(X, m), \text{ supp } \mu \subseteq G(\leq) \} \) contains the multiplication algebra \( \mathcal{M} = \{ M_h : h \in L^0(X, m) \} \) and is an \( \mathcal{M} \) bimodule. To see this, define a measure \( \mu_h \) supported on the diagonal \( \Delta = \{ (x, x) : x \in X \} \) by

\[ \mu_h(A) = \int_{x \in (A \cap \Delta)} h \, dm. \]

The marginal measures are \( |\mu_h|_1 = |\mu_h|_2 = \| h \|_d \). So \( \mu_h \) belongs to \( \mathcal{A}(X, m) \). For any \( f \) and \( g \) in \( L^0(X, m) \), one has

\[ (T_{\mu_h}f, g) = \int \int f(y)g(x) \, dm(x). \]

Let \( \mu \) be any measure in \( \mathcal{A}(X, m) \). The measure \( \nu = h_1(x)h_2(y)\mu \) has support contained in \( \text{supp } \mu \), and marginals \( |\nu|_1 \leq h_1 \| h_2 \| \| \mu \|_1 \) and \( |\nu|_2 \leq \| h_1 \| \| h_2 \| \| \mu \|_2 \). Again, for \( f \) and \( g \) in \( L^0(X, m) \), compute

\[ (T_\nu f, g) = \int \int f(y)g(x) \, dm(x). \]

So \( M_{h_1}T_\mu M_{h_2} = T_\nu \).

Let \( \mathcal{A}_{\text{min}}(X, \leq, m) \) be the weak* closed algebra generated by

\[ \{ T_\mu : \mu \in \mathcal{A}(X, m), \text{ supp } \mu \subseteq G(\leq) \}. \]

This is, in fact, the weak* closed linear span (see Appendix 22.31). The previous remarks show that \( \mathcal{A}_{\text{min}}(X, \leq, m) \) contains the multiplication algebra \( \mathcal{M} \). The notation \( \text{min} \) will be justified in Theorem 22.16.

22.9 Theorem. Let \( \mathcal{A}_{\text{min}}(X, \leq, m) = L(X, \leq, m) \).

Proof. Let \( P \) be a projection onto an invariant subspace of \( \mathcal{A}_{\text{min}} \). This is also invariant for \( \mathcal{M} \), and thus \( P \) belongs to \( \mathcal{M} \); so \( P = P(E) \) is multiplication by the characteristic function of a Borel set \( E \). Choose an increasing sequence \( K_n \) of compact subsets of \( E \) so that \( m(E \setminus \bigcup K_n) = 0 \). Likewise, choose an increasing sequence \( C_n \) of compact subsets of \( E^c \) with
\[ m(E^c \setminus \bigcup C_n) = 0. \] For every \( T_\mu \) in \( \mathcal{A}_{\text{min}} \),

\[
0 = P(C_n)(P(E) \perp T_\mu P(E))P(K_n) = P(C_n)T_\mu P(K_n) = T_{\mu_n}
\]

where \( \mu_n = \mu | C_n \times K_n \). Thus there is no non-zero measure \( \mu \) in \( \mathcal{A}(X,m) \) supported on \( (C_n \times K_n) \cap G(\leq) \). By Theorem 22.8, this set is marginally null. Now, \( E^c \times E \cap G(\leq) \) is contained in

\[
(E^c \setminus \bigcup_{n \geq 1} C_n) \times X \cup X \times (E \setminus \bigcup_{n \geq 1} K_n) \cup \bigcup_{n \geq 1} (C_n \times K_n) \cap G(\leq)
\]

which is a countable union of marginally null sets, and thus is marginally null.

Let \( N \) be a Borel set with \( m(N) = 0 \) so that \( E^c \times E \cap G(\leq) \subseteq (N \times X) \cup (X \times N) \).

Let \( \pi_i \) be the coordinate projections of \( X^2 \) onto \( X \). Define

\[
F = (E \setminus N)^+ = \{ x : \exists y \in E \setminus N, y \leq x \}
\]

\[
= \pi_1(\pi_2(E \setminus N) \cap G(\leq))
\]

\[
= (E \setminus N) \cup \pi_1(E^c \cup N) \times (E \setminus N) \cap G(\leq)
\]

\[
\subseteq E \setminus N \cup N = E \cup N.
\]

Thus \( F \) is an increasing set such that \( m(E \Delta F) = 0 \), whence \( P(E) = P(F) \) belongs to \( L(X, \leq, m) \).

The inclusion of \( L(X, \leq, m) \) in \( \text{Lat} \mathcal{A}_{\text{min}} \) is immediate from Theorem 22.5, so the theorem follows.

\[ \Box \]

**22.10 Corollary.** \( L(X, \leq, m) \) is reflexive.

**Proof.**

\[
L(X, \leq, m) \subseteq \text{Lat Alg} L(X, \leq, m)
\]

\[
\subseteq \text{Lat} \mathcal{A}_{\text{min}}(X, \leq, m) = L(X, \leq, m).
\]

\[ \Box \]

**22.11 Corollary.** Every commutative subspace lattice on a separable Hilbert space is reflexive.

**Proof.** Apply Theorem 22.4 and Corollary 22.10.

We now turn to the consideration of \( \mathcal{M} \) bimodules, where \( \mathcal{M} \) is a masa containing \( L^n = \{ P(L) : L \in L \}^n \), which have \( L \) as its lattice. Two such modules are \( \text{Alg} L \) and \( \mathcal{A}_{\text{min}}(L) \). As in Chapter 15, we will use the infinite ampliation \( S \otimes I \) of a weak* closed module \( S \) in order to work
with reflexive subspaces (Lemma 15.4).

Given a commutative subspace lattice \( L \) of \( \mathcal{H} \), consider two lattices of \( \mathcal{H} \otimes \mathcal{H} \). Let \( L \otimes \text{Proj}(\mathcal{H}) \) denote the strongly closed (complete) lattice of projections generated by \( \{P(L) \otimes Q : L \in L, Q \in \text{Proj}(\mathcal{H})\} \). Let \( L \otimes \text{Proj}(\mathcal{H}) \) denote the lattice of projections \( P \) in \( \text{Proj}(\mathcal{H} \otimes \mathcal{H}) \) such that \((I \otimes E)P(I \otimes E)\) belongs to the closed convex hull \( \text{conv}\{P(L) \otimes E : L \in L\} \) for every rank one projection \( E \) in \( \text{Proj}(\mathcal{H}) \). It is not immediate that this latter set is a lattice, but it is strongly closed and contains \( P(L) \otimes Q \) for all \( L \in L \) and \( Q \in \text{Proj}(\mathcal{H}) \). So once it is shown to be a lattice, it will follow that it contains \( L \otimes \text{Proj}(\mathcal{H}) \).

By Theorem 22.4, we can identify \( L \) with \( L(X, \leq m) \) acting on \( L^2(X, m) \). By Lemma 15.3, \( L^2(X, m) \otimes \mathcal{H} \) is naturally identified with \( L^2(X, \mathcal{H}, m) \), the space of square integrable functions on \( X \) with values in \( \mathcal{H} \). This identification takes \( L^2(X, m) \otimes B(\mathcal{H}) \) onto \( L^2(X, B(\mathcal{H}), m) \). For example, if \( E \) is an increasing set and \( Q \) is a projection in \( B(\mathcal{H}) \), then \( P(E) \otimes Q \) is identified with the function \( f = Q\chi_E \) which is an increasing function into \( B(\mathcal{H})_+ \) in the sense that \( x \geq y \) implies \( f(x) \geq f(y) \). A function \( f \) is essentially increasing if it agrees with an increasing function a.e. \((m)\).

22.12 Lemma. The closed convex hull of \( L(X, \leq m) \) is weak* closed, and coincides with the set of operators \( M_f \) for (essentially) increasing \( f \) in \( L^\infty(X, m) \) such that \( 0 \leq f \leq 1 \).

Proof. Each \( \chi_E \) for \( P(E) = M_{\chi_E} \) in \( L(X, \leq m) \) is an increasing function with \( 0 \leq \chi_E \leq 1 \). Thus the same holds for the weak* closed convex hull. Conversely, if \( f \) is increasing, then \( E_r = \{x : f(x) \geq r\} \) is an increasing set. The operators

\[
M_{f,n} = \frac{1}{n} \sum_{k=1}^{n} P(E_k/n)
\]

are in \( \text{conv}(L(X, \leq m)) \), and \( 0 \leq f - f_n \leq 1/n \). So \( M_f \) is in the norm closed convex hull of \( L(X, \leq m) \).

22.13 Corollary. \( L(X, \leq m) \otimes \text{Proj}(\mathcal{H}) \) consists of all (essentially) increasing, projection valued functions in \( L^\infty(X, B(\mathcal{H}), m) \). Consequently, it forms a complete lattice.

Proof. Let \( P \) be an increasing projection valued function in \( L^\infty(X, B(\mathcal{H}), m) \) and let \( E \) be the rank one projection onto \( \mathcal{E} \xi \) in \( \mathcal{H} \). Then

\[
(I \otimes E)P(I \otimes E)(x) = EP(x)E = (P(x)\xi, \xi)E.
\]

As \( P(x) \) is increasing, \( f(x) = (P(x)\xi, \xi) \) is an increasing function with \( 0 \leq f \leq 1 \). So \( f(E) = M_f \otimes E \) belongs to \( \text{conv}\{P(L) \otimes E : L \in L\} \) by
Lemma 22.12.

Conversely, if \( P \) is a projection on \( L^\infty(X,B,I,m) \) such that 
\((I \otimes E)P(I \otimes E)\) belongs to \( \text{conv}\{P(L) \otimes E : L \in L\} \) for all rank one 
projections \( E \), one deduces as above that 
\( f(x) = (P(x)\xi,\xi) \) is increasing 
for every \( \xi \) in \( \mathcal{H} \). Thus \( x \geq y \) implies 
\( (P(x)\xi,\xi) \geq (P(y)\xi,\xi) \) for all \( \xi \), 
whence \( P(x) \geq P(y) \). So \( P \) is an increasing projection valued function.

It is not difficult to see that this forms a complete, strongly closed 
lattice where the lattice operations are performed pointwise. (If one wishes 
to pick an arbitrary representing function instead of an increasing one, 
then one must deal with “almost everywhere”, which is a technical nui-
sance but not a serious difficulty.) ■

22.14 Lemma. Let \( \mu \) belong to \( A(X,m) \), and let \( F, G \) belong to 
\( L^2(X,H,m) \). Then 
\[(T_\mu \otimes I)F \otimes G = \int \chi_x(F(y),G(x))d\mu(x,y) .\]

Proof. Since \( |(F(y),G(x))| \leq ||F|| \cdot ||G|| \), the right hand side is integrable 
uniformly on the unit ball. Suppose \( F = \sum_{i=1}^{n} f_i \otimes u_i \) and 
\( G = \sum_{j=1}^{m} g_j \otimes v_j \) 
where \( f_i, g_j \) belong to \( L^2(X,m) \) and \( u_i, v_j \) belong to \( \mathcal{H} \). Then 
\[(T_\mu \otimes I)F \otimes G = \sum_{i=1}^{n} \sum_{j=1}^{m} (T_{\mu}f_i, g_j)(u_i,v_j) \]
\[= \sum_{i=1}^{n} \sum_{j=1}^{m} \int \chi_x f_i(y) \overline{g_j(x)}d\mu(x,y)(u_i,v_j) \]
\[= \int \chi_x F(y),G(x))d\mu(x,y) . \]

Such vectors are dense in \( L^2(X,H,m) \) and both sides converge uniformly. 
Thus the formula is valid in general. ■

22.15 Lemma. \( \text{Lat}(A_{\text{min}}(L) \otimes I) \) contains \( L \otimes \text{Proj}(H) \).

Proof. By Theorem 22.4, we may assume that \( L = L(X,\leq,m) \). Let \( T_\mu \) 
belong to \( A_{\text{min}}(X,\leq,m) \) and fix \( P \) in \( L \otimes \text{Proj}(H) \). Let \( F = PF \) and 
\( G = P^\perp G \) be vectors in the range of \( P \) and \( P^\perp \) respectively. Then for all 
\((x,y) \in G(\leq), y \leq x \) whence \( P(y) \leq P(x) \); so \( P(x)^\perp P(y) = 0 \). Thus
\((T_\mu \otimes I)^F,G\) = \(\int \int_X A(F(y),G(x))d \mu(x,y)\)
\[= \int \int_{\gamma \leq \gamma}(P(y)F(y),P(x)^{-1}G(x))d \mu(x,y)\]
\[= \int \int_{\gamma \leq \gamma}(P(x)^{-1}P(y)F(y),G(x))d \mu(x,y) = 0 .\]
Consequently, \(P^{-1}(T_\mu \otimes I)P = 0\) as desired. \(\Box\)

The stage is now set to prove the minimality of \(A_{\text{min}}\).

22.16 Lemma. Let \(A\) be a weak* closed algebra containing a masa \(M\) with \(\text{Lat } A = L\). Then \(\text{Lat } A \otimes I\) is contained in \(L \otimes \text{Proj}(H)\).

Proof. Let \(P\) be a projection onto some element of \(\text{Lat } A \otimes I\). This is, a fortiori, invariant for \(M \otimes I\). So by Theorem 15.1, \(P\) belongs to \(M \otimes B(\mathcal{H})\). Also note that \(M\) commutes with \(L\), and hence contains \(L\). Let \(E\) be the projection of \(H\) onto \(C\xi\) for a given unit vector \(\xi\). Then \((I \otimes E)P(I \otimes E) = M \otimes E\), where \(M\) is a positive contraction in \(M\). Let \(A\) belong to the unit ball of \(A\), and let \(x\) be a vector.

\[(AMA^*x, x) = ((A \otimes I)(I \otimes E)P(I \otimes E)(A^* \otimes I)x \otimes \xi, x \otimes \xi)\]
\[= \|P(A^* \otimes I)x \otimes \xi\|^2\]
\[= \|P(A^* \otimes I)P(x \otimes \xi)\|^2\]
\[\leq \|P(x \otimes \xi)\|^2\]
\[= \|(I \otimes E)P(I \otimes E)x \otimes \xi, x \otimes \xi\) = (Mx, x) .\]
Thus \(AMA^* \leq M\).

Let \(E_r = E_M[r,1]\) denote the spectral projection of \(M\) for the interval \([r,1]\), and let \(P_r\) be the least projection in \(L\) dominating \(E_r\). This is the projection onto \(AE_r, \mathcal{H}\). If \(F\) is any projection in \(M\) with \(F \leq P_r\), there is an operator \(A\) in \(A\) so that \(FAE_r \neq 0\). Normalize so that \(B = FAE_r\) has norm one. Then
\[rBB^* = B(rE_r)B^* = BMB^* \leq M .\]
Hence \(\|FM\| \geq r\|FBB^*F\| = r\) for every \(F \leq P_r\), and thus \(M \geq rP_r\). This implies that \(E_r \geq P_r \geq E_r\); that is, \(E_r\) belongs to \(L\) for all \(r \geq 0\). Thus \(M = \int \gamma E_r dr\) belongs to \(\text{conv}(L)\). Therefore, \(P\) belongs to \(L \otimes \text{Proj}(H)\). \(\Box\)

22.17 Theorem. Let \(A\) be a weak* closed algebra containing a masa \(M\) with \(\text{Lat } A = L\). Then \(A_{\text{min}}(L) \subseteq A \subseteq \text{Alg } L\). Conversely, every weak* closed algebra in this interval has \(\text{Lat } A = L\), and contains \(L'\).
Proof. By Lemmas 22.15 and 22.16, \( \text{Lat } A \otimes I \) is contained in \( \text{Lat } A_{\text{min}} \otimes I \). By Lemma 15.4, both inflated algebras are reflexive. Hence \( A_{\text{min}}(L) \) is contained in \( A \), which in turn contained in \( \text{Alg } L \). By Theorem 22.9, \( \text{Lat } A_{\text{min}} = L \). Lemma 22.15 and 22.16 show that \( \text{Lat } A_{\text{min}} \otimes I \) equals \( L \otimes \text{Proj}(\mathcal{H}) \) which is contained in \( L'' \otimes B(\mathcal{H}) \). By Theorem 15.1, the commutant of \( L'' \otimes B(\mathcal{H}) \) is \( L' \otimes I \). Another application of Lemma 15.4 shows that \( A_{\text{min}} \) contains \( L' \). So the converse follows. ■

22.18 Corollary. If \( A \) is a weak* closed algebra containing a masa such that \( \text{Lat } A = L \), then the diagonal \( \text{A} \cap \text{A}^* = L' \).

Proof. \( L' \subseteq A_{\text{min}}(L) \cap A_{\text{min}}(L)^* \subseteq A \cap \text{A}^* \subseteq \text{Alg } L \cap (\text{Alg } L)^* = L' \). ■

The methods used above are closely related to the results of Chapter 15, part B. However, in the case of nests, we avoided the measure theoretic difficulties. Also, we still have not recovered the results of that chapter for two reasons. One is that we have only considered algebras, not general \( M \) bimodules. But more importantly, we have not discussed when \( A_{\text{min}}(L) = \text{Alg } L \), even for nests.

22.19 Theorem. Let \( M \) be a masa, and let \( L \) be a commutative subspace lattice. Suppose that \( S \) is a weak* closed \( M \)-bimodule such that \( Sx = (\text{Alg } L)x \) for all \( x \) in \( \mathcal{H} \). Then \( S \) contains \( A_{\text{min}}(L) \).

Proof. Form the algebra \( B(S) \) of all operators of the form \[
\begin{bmatrix}
M_1 & S \\
0 & M_2
\end{bmatrix},
\]
where \( M_1, M_2 \) belong to \( M \) and \( S \) belongs to \( S \). This is weak* closed and contains the masa \( M \oplus M \). A simple computation shows
\[
\text{Lat } B(S) = \{ L_1 \oplus L_2 : L_1 \in \text{Lat } M, L_1 \supseteq S_{L_2} \}
\]
\[
= \{ L_1 \oplus L_2 : L_1 \in \text{Lat } M, L_1 \supseteq (\text{Alg } L)L_2 \} = L_2.
\]
By Theorem 22.17, \( B(S) \) contains \( A_{\text{min}}(L_2) \). From Theorem 22.9, it follows that \( A_{\text{min}}(L) \) satisfies the hypothesis of this theorem. So \( B(A_{\text{min}}(L)) \) also contains \( A_{\text{min}}(L) \).

By Theorem 22.4 and its proof, we may suppose that \( L = L(X, \leq, m) \) and \( M = L^\infty(X, m) \). Let \( X^{(b)} = X \cup Y \) denote the disjoint union of two copies of \( X = Y \). Denote the elements of \( X \) by \( x, x_1, x_2, \ldots \) and the elements of \( Y \) by \( y, y_1, y_2, \ldots \). Define a partial order \( \ll \) on \( X^{(b)} \) by
\[ x_1 \ll x_2 \iff x_1 = x_2 , \]
\[ y_1 \ll y_2 \iff y_1 = y_2 , \]
\[ x \ll y , \]
\[ y \ll x \iff y \leq x \text{ in } X . \]

One readily verifies that \( L_2 = L(X^{(2)}, \ll , m \oplus m) \) and \( \mathcal{M} \oplus \mathcal{M} = L^\infty(X^{(2)}, m \oplus m) \). By Corollary 22.13, \( L_2 \otimes \text{Proj}(\mathcal{M}) \) consists of all projection valued functions \( P = P_1 \oplus P_2 \) in \( L^\infty(X^{(2)}, B(\mathcal{M})) \) such that
\[ P_1(x) \geq P_2(y) \text{ if } x \geq y . \]

Consider an operator \( T = \begin{bmatrix} M_1 & A \\ 0 & M_2 \end{bmatrix} \) in \( \text{Alg}(L_2) \). Then
\[ P_\perp(T \otimes I)P = \begin{bmatrix} 0 & P_\perp(A \otimes I)P_2 \\ 0 & 0 \end{bmatrix} . \]

If \( A = T_\mu \) for \( \mu \) in \( A(X,m, \leq) \), let \( F = P_2F \) and \( G = P_\perp G \) in \( L^2(X,m) \). One obtains by Lemma 22.14
\[ ((T_\mu \otimes I)F,G) = \int \int (F(y),G(x))d\mu \]
\[ = \int \int (P_\perp(x)P_2(y)F(y),G(x))d\mu = 0 . \]

Thus \( \begin{bmatrix} M_1 & T_\mu \\ 0 & M_2 \end{bmatrix} \) belongs to \( \mathcal{A}_{\min}(L_2) \). By the Appendix 22.31, these operators are weak* dense in \( B(\mathcal{A}_{\min}(L_2)) \). Hence \( \mathcal{A}_{\min}(L_2) = B(\mathcal{A}_{\min}(L_2)) \). Consequently, \( S \) contains \( \mathcal{A}_{\min}(L_2) \).

A commutative subspace lattice is called synthetic if \( \mathcal{A}_{\min}(L) = \text{Alg}(L) \). By Theorem 15.11 (or Proposition 22.23 below), every nest is synthetic. A lattice \( L \) is complemented if \( L \subseteq L \) implies \( L_\perp \subseteq L \). The lattice is atomic if \( L'' \) is atomic. A lattice \( L \) will be called finite width if it is generated as a lattice by finitely many commuting nests. It will be called width \( n \) if \( n \) is the least number of nests required to generate \( L \) as a lattice.

22.20 Proposition. Every complemented CSL is synthetic.

Proof. If \( L \) is complemented, then \( \text{Alg} L = L' \) is a von Neumann algebra. The proposition is immediate from Corollary 22.18.
22.21 Lemma. Every Hilbert-Schmidt operator in $\text{Alg}(L)$ belongs to $A_{\min}(L)$.

Proof. Represent $L$ as $L(X, \leq m)$ by Theorem 22.4. Each Hilbert-Schmidt operator $K$ on $L^2(m)$ has an $L^2$ kernel $\mu = k(x,y)dm \times m$. This operator belongs to $\text{Alg}(L)$ if and only if $\mu$ is supported on the graph of the pre-order $G(\leq)$ (compare with Theorem 22.5). The marginal measures are bounded if $k(x,y)$ is bounded. So let $k_n = \chi_n \circ k$ where $X_n$ is the characteristic function of $\{x: |x| \leq n\}$. Clearly, $k_n$ converges to $k$ in $L^2$. Thus, $K_n = T_{k_n} dm \times m$ belong to $A_{\min}(L)$ and converge in norm to $K$. So $K$ belongs to $A_{\min}(L)$.

22.22 Proposition. Every atomic CSL is synthetic.

Proof. If $L$ is atomic, then $L'$ contains a sequence of finite rank projections $P_n$ converging strongly to the identity. For each $T$ in $\text{Alg}(L)$, $TP_n$ is a sequence of finite rank operators in $\text{Alg}(L)$ converging strongly to $T$. By Lemma 22.20, $TP_n$ belong to $A_{\min}(L)$. Thus $T$ does also. So $A_{\min}(L) = \text{Alg}(L)$.

22.23 Proposition. Every nest is synthetic.

Proof. By the Erdos Density Theorem 3.11, the finite rank operators in $T(\mathcal{N})$ are strongly dense. By Lemma 22.21, these finite rank operators belong to $A_{\min}(\mathcal{N})$. Whence $A_{\min}(\mathcal{N}) = T(\mathcal{N})$.

22.24 Lemma. Let $L$ be a synthetic CSL and let $\mathcal{N}$ be a nest commuting with $L$. For every $N$ in $\mathcal{N}$, $P(N)\text{Alg}(L)P(N)^\perp$ is contained in $A_{\min}(L \vee \mathcal{N})$.

Proof. By Theorem 22.4, we may assume that $L \vee \mathcal{N} = L(X, \leq m)$ acting on $L^2(X, m)$. Let $T_\mu$ be a pseudo-integral operator in $\text{Alg}(L)$. Then since $P(N)$ belongs to $(L \vee \mathcal{N})^\text{\#} \subseteq L^\infty(X, m)$, and the pseudo-integral operators form an $L^\infty(X, m)$ bimodule, $P(N)T_\mu P(N)^\perp$ is a pseudo-integral operator $T_\nu$. Furthermore, $T_\nu$ belongs to $\text{Alg}(L) \cap T(\mathcal{N}) = \text{Alg}(L \vee \mathcal{N})$. By Theorem 22.5, $T_\nu$ belongs to $A_{\min}(L \vee \mathcal{N})$. Since $L$ is synthetic, each $T$ in $\text{Alg}(L)$ is the weak* limit of a net $T_{\mu_\alpha}$ in $\text{Alg}(L)$. Thus if $P(N)T_{\mu_\alpha}P(N)^\perp = T_{\nu_\alpha}$, $P(N)TP(N)^\perp = w^*\lim_{\alpha} T_{\nu_\alpha}$ belongs to $A_{\min}(L \vee \mathcal{N})$.

22.25 Lemma. Let $L$ be a synthetic CSL, and let $\mathcal{N}$ be a nest commuting with $L$. If $L \vee \mathcal{N} \vee \mathcal{N}^\perp$ is synthetic, then $L \vee \mathcal{N}$ is also synthetic.
Proof. Let \( \{N_k, k \geq 1\} \) be a strongly dense subset of \( \mathcal{N} \). For each \( n \), let \( E^{(n)}_i \) be the atoms of the finite nest \( \mathcal{I}_n \) consisting of \( \{0, \mathcal{N}, N_1, \ldots, N_n\} \). Fix \( T \) in \( \text{Alg}(L \lor \mathcal{N}) \), and define \( R_n = \Delta T_s(T) \) and

\[
S_n = T - R_n = \sum_{i \neq j} E^{(n)}_i T E^{(n)}_j .
\]

Now, \( E^{(n)}_i T E^{(n)}_j \neq 0 \) only if \( E^{(n)}_i \ll E^{(n)}_j \), so \( E^{(n)}_i T E^{(n)}_j \) belongs to \( \mathcal{A}_{\min}(L \lor \mathcal{N}) \) by the previous lemma. Thus \( S_n \) belongs to \( \mathcal{A}_{\min}(L \lor \mathcal{N}) \).

Since \( \| R_n \| \leq \| T \| \), we may drop to a subsequence so that \( R = w^*-\lim R_{n_k} \) exists. Clearly, \( R \) commutes with \( \mathcal{N} \) and belongs to \( \text{Alg}(L \lor \mathcal{N}) \), and hence belongs to \( \text{Alg}(L \lor \mathcal{N} \lor \mathcal{N}^\perp) = \mathcal{A}_{\min}(L \lor \mathcal{N} \lor \mathcal{N}^\perp) \). This is contained in \( \mathcal{A}_{\min}(L \lor \mathcal{N}) \). Also, \( S = T - R = w^*-\lim S_{n_k} \) belongs to \( \mathcal{A}_{\min}(L \lor \mathcal{N}) \), whence \( T \) does. But \( T \) is arbitrary, so \( L \lor \mathcal{N} \) is synthetic. \( \blacksquare \)

22.26 Theorem. Every finite width CSL lattice is synthetic.

Proof. We show that if \( L \) has finite width and \( B \) is a Boolean algebra commuting with \( L \), the \( L \lor \mathcal{N} \) is synthetic. The special case \( B = \{0, I\} \) yields the desired result. Proceed by induction on \( n \), the width of \( L \). For \( n = 1 \), \( L \) is a chain. So \( B = B \lor L \lor L^\perp \) are Boolean algebras, and hence are synthetic by Proposition 22.20. Hence \( B \lor L \) is synthetic by Lemma 22.25. Now assume the result for width \( n \), and let \( L \) have width \( n+1 \). Write \( L = L_0 \lor \mathcal{N} \) where \( L_0 \) has width \( n \) and \( \mathcal{N} \) is a nest. Then \( B \lor \mathcal{N} \lor \mathcal{N}^\perp = B \lor L \lor L^\perp \) are Boolean algebras. By the induction hypothesis, both \( L_0 \lor B \lor \mathcal{N} \lor \mathcal{N}^\perp \) and \( L_0 \lor B \lor \mathcal{N} \lor \mathcal{N}^\perp \) are synthetic. Hence by Lemma 22.25, \( L_0 \lor B \lor \mathcal{N} = L \lor B \) is synthetic. \( \blacksquare \)

There are examples of lattices \( L \) which are not synthetic. The known examples are all related to sets of spectral synthesis in commutative harmonic analysis. A discussion of this is contained in the notes at the end of this chapter.

We now consider the question of generators, and extend the result for nests (Corollary 15.17) to arbitrary CSL's.

22.27 Theorem. Let \( L \) be a commutative subspace lattice, and let \( \mathcal{M} \) be a masa containing \( L^n \). Then \( \mathcal{A}_{\min}(L) \) is singly generated as an \( \mathcal{M} \) bimodule.

Proof. By Theorem 22.4, we may represent \( L \) as \( L(X, \leq, m) \) and \( \mathcal{M} \) as \( L^\omega(X, m) \). The unit ball of \( B(\mathcal{N}) \) in the weak* topology is metrizable and hence separable. So one can choose pseudo-integral operators \( \{T_{\mu_n} : n \geq 1\} \) in the unit ball of \( \mathcal{A}_{\min}(L) \) which are weak* dense in the ball of \( \mathcal{A}_{\min}(L) \) (because of Appendix 23.35). Let \( \mu = \sum_{n \geq 1} 2^{-n} \frac{|\mu_n|}{\|\mu_n\|} \). This is a finite
measure in $A(X, \leq, m)$. It has the property that if $E$ and $F$ are measurable subsets of $X$ such that $(E \times F) \cap G(\leq)$ is not marginally null, then $\mu(E \times F) > 0$. To see this, note that $\mu(E \times F) = 0$ forces $\mu_n(E \times F) = 0$ for all $n$, whence $P(E)T_\mu P(F) = 0$ for all $n$. From their density, we deduce that $P(E)A_{\text{min}}(L)P(F) = 0$. From Theorem 22.8, we get that $(E \times F) \cap G(\leq)$ is marginally null.

For any vector $x$ in $\mathcal{H}$, let $P(E)$ be the projection onto $\mathcal{M}x$, and let $P(L)$ be the projection onto $\mathcal{MT}_\mu S\mathcal{M}x$. Since $P(L)^{-1}T_\mu P(E) = 0$, we have $P(L)^{-1}A_{\text{min}}(L)P(E) = 0$. Hence

$$P(L)\mathcal{H} \supseteq A_{\text{min}}(L)x \supseteq \mathcal{MT}_\mu \mathcal{M}x = P(L)\mathcal{H}.$$ 

By Theorem 22.19, the weak* closure of $\mathcal{MT}_\mu \mathcal{M}$ contains $A_{\text{min}}(L)$. The reverse inclusion is obvious. So $T_\mu$ generates $A_{\text{min}}(L)$ as an $\mathcal{M}$ bimodule. ■

22.28 Corollary. Let $L$ be a commutative subspace lattice. Then $A_{\text{min}}(L)$ is doubly generated as a weak* closed algebra.

Proof. Take $\mathcal{M}$ to be any masa containing $L''$. Take $A$ to be a self-adjoint generator of $\mathcal{M}$, and take $T_\mu$ as above. Then $\{A, T_\mu\}$ generate $A_{\text{min}}(L)$ as an algebra. ■

We wish to define the notation of support of an operator acting on $L^q(X, m)$. Then we will relate this to certain $L^q(X, m)$ bimodules. The support of $T$ is the (closed set) of points $(x, y)$ in $X \times X$ such that for every neighbourhood $U \times V$ of $(x, y)$, $P(U)TP(V) \neq 0$. Equivalently, the complement of the support is the union of all open sets $U \times V$ of $X \times X$ such that $P(U)TP(V) = 0$.

Given a closed subset $F$ of $X \times X$, let $A_{\text{min}}(F)$ denote the weak* closure of $\{T_\mu: \text{supp}(\mu) \subseteq F\}$. Let

$$A_{\text{max}}(F) = \{T \in B(L^q(m)): \text{supp}(T) \subseteq F\}.$$ 

Recall (15.B) that a subspace $S$ of $B(\mathcal{H})$ is called reflexive if $Tx \in \overline{Sx}$ for all $x$ in $\mathcal{H}$ implies that $T$ belongs to $S$. The reflexive hull of $S$, denoted $\text{ref}(S)$, is the smallest reflexive subspace containing $S$. This is precisely $\{T \in B(\mathcal{H}): Tx \in \overline{Sx} \text{ for all } x \in \mathcal{H}\}$.

22.29 Theorem. Let $F$ be a closed subset of $X \times X$. Then $\text{ref}(A_{\text{min}}(F)) = A_{\text{max}}(F)$. If $S$ is a weak* closed $L^q(X, m)$ bimodule such that $Sx = A_{\text{min}}(F)x$ for all $x$ in $\mathcal{H}$, then $A_{\text{min}}(F) \subseteq S \subseteq A_{\text{max}}(F)$.

Proof. Suppose $Tx$ belongs to $\overline{A_{\text{min}}(F)x}$ for every $x$ in $\mathcal{H}$. Let $U \times V$ be an open set disjoint from $F$. Then for $\mu$ supported on $F, f, g$ in $L^q(m)$,
\[(P(U)T_\mu P(V)f,g) = \int \int \mathcal{F} f(y)\overline{g(z)} d\mu = 0 .\]

Thus \(P(U)T_\mu P(V) = 0\) for all such \(\mu\), hence \(P(U)TP(V) = 0\). Thus supp\((T)\) is contained in \(F\). Hence ref\(\left(\mathcal{A}_{\min}(F)\right)\) is contained in \(\mathcal{A}_{\max}(F)\).

Now suppose that supp\((T)\) is contained in \(F\). For any closed set \(A \times B\) disjoint from \(F\), a standard compactness argument produces a finite open cover \(\{U_i \times V_i: 1 \leq i \leq n\}\) of \(A \times B\) disjoint from \(F\). Thus it follows from \(P(U_i)TP(V_i) = 0, 1 \leq i \leq n\), that \(P(A)TP(B) = 0\). Next, suppose that \(A \times B\) is a Borel rectangle disjoint from \(F\). By the regularity of \(m\), one can choose increasing sequences of closed sets \(A_n, B_n\) such that \(m(A \cup A_n) = 0\) in \((B \cup B_n)\). Thus

\[P(A)TP(B) = \lim_{n \to \infty} P(A_n)TP(B_n) = 0 .\]

Fix a vector \(x\) in \(\mathcal{H}\). Let \(L^\infty(X,m)x = L^2(B), \mathcal{A}_{\min}(F)x = L^2(A_1)\), and \(A_{\max}(F)x = L^2(A_0)\); and set \(A = A_2 \setminus A_1\). Since \(P(A)TP(B) = 0\) for every \(\mu\) in \(\mathcal{A}(X,m)\) supported on \(F\), it follows that \((A \times B) \cap F\) does not support any non-zero measure in \(\mathcal{A}(X,m)\). If \(A_n\) and \(B_n\) are compact sets as above, Theorem 22.8 shows that \((A_n \times B_n) \cap F\) is marginally null for all \(n\). Hence \((A \times B) \cap F\) is marginally null. Let \(N\) and \(M\) be null sets so that

\[(A \times B) \cap F \subseteq (N \times X) \cup (X \times M) .\]

Then \(F\) is disjoint from \((A \setminus N) \times (B \setminus M)\). By the previous paragraph, \(P(A)TP(B) = 0\) for all \(T\) in \(\mathcal{A}_{\max}(F)\). This occurs only if \(P(A) = 0\). So \(\mathcal{A}_{\max}(F)\) is contained in ref\(\left(\mathcal{A}_{\min}(F)\right)\), and equality follows.

We will now make use of Theorem 22.19 and its proof. As before, let \(B\) denote the algebra of all operators of the form

\[
\begin{bmatrix}
M_1 & S \\
0 & M_2
\end{bmatrix}, \quad M_i \in L^\infty(X,m), \quad S \in S .
\]

This is weak* closed and contains the masa \(L^\infty(X,m) \oplus L^\infty(X,m)\). Let \(X^{(2)} = X \cup Y\) denote the disjoint union of two copies of \(X = Y\). Denote the elements of \(X(Y)\) by \(x, x_1, x_2, (y, y_1, y_2)\). Define a pre-order \(\ll\) on \(X^{(2)}\) by

\[x_1 \ll x_2 \Leftrightarrow x_1 = x_2 ,\]

\[y_1 \ll y_2 \Leftrightarrow y_1 = y_2 ,\]

\[x \perp y,
\]

\[y \ll x \Leftrightarrow (x, y) \in F .\]

It is immediately apparent that the graph of this pre-order is

\[\{(x,x): x \in X\} \cup \{(y,y): y \in Y\} \cup \{(x,y): x \in X, y \in Y, (x,y) \in F\} .\]

Consequently, \(\mathcal{A}_{\min}(L(X^{(2)}, \ll, m \oplus m)) = B(\mathcal{A}_{\min}(F))\).
By the proof of Theorem 22.19, if $S$ is a weak* closed $L^\infty(X,m)$ bimodule such that $Sx = A_{\text{min}}(F)x$ for all $x$ in $\mathcal{H}$, then $\text{Lat} \ B \ (S) = L(X^{[m]}, \leq, m \oplus m)$. Hence $S$ contains $A_{\text{min}}(F)$ and is contained in $\text{ref}(A_{\text{min}}(F)) = A_{\text{max}}(F)$. 

22.30 Corollary. $\text{Alg} (L(X, \leq, m))$ consists of all operators supported on $G(\leq)$. 

22.31 Appendix.

This section is devoted to the proof that there is a multiplication $*$ on $A(X,m)$ such that $T_\mu T_\nu = T_{\mu \nu}$, hence it will follow that $A_{\text{min}}(X, \leq, m)$ equals the weak* closed linear span $S_0$ of $(T_\mu; \mu \in A(X,m), \text{supp}(\mu) \subseteq G(\leq))$. The proof is long and technical, and we feel that a simpler proof should be possible. Indeed, the proof of Theorem 22.19 shows that $S_0$ consists of all operators $T$ such that $Q^* (T \otimes I)P = 0$ whenever $P$, $Q$ are projections in $L^\infty(X,B(\mathcal{H}))$ such that $x \leq y$ implies $P(x) \leq Q(y)$. Whereas Lemmas 22.15 and 22.16 show that $A_{\text{min}}(X, \leq, m)$ consists of all operators $T$ such that $R^* (T \otimes I)P = 0$ whenever $P$, $R$ are projections in $L^\infty(X,B(\mathcal{H}))$ such that $x \leq y$ implies $P(x) \leq R(x) \leq R(y)$. Since $L \otimes \text{Proj}(\mathcal{H})$ is a complete lattice, there is a least projection $R$ with this property, namely the projection onto $(A_{\text{min}} \otimes I) \text{Ran}(P)$. If it were shown that there is a set $N$ with $m(N) = 0$ so that for $x \notin N$, 

$$R(x) = \sup_{y \leq x, y \in N} P(y)$$

then it follows that every $Q$ as above satisfies $Q \geq R$. Hence $A_{\text{min}}$ equals $S_0$.

To prove this directly, we require a formula for $T_\mu f$. The following theorem is taken from Dunford and Schwartz [1], Theorem VI.8.6.

22.32 Theorem (Dunford-Pettis). Let $B$ be a separable Banach space, and let $(X,m)$ be a $\sigma$-finite measure space. Let $T$ be a bounded linear operator from $L^1(m)$ into $B^*$. There is an essentially unique Borel function $B : X \to B^*$ such that $\text{ess.sup} \|B(x)\| = \|T\|$, and for each $f \in L^1(m)$ and $b \in B$, 

$$(Tf)(b) = \int \langle B(x), b \rangle f(x) \, dm(x).$$

This is the key ingredient in the following “disintegration of measures” theorem. For greater detail and greater generality, consult Bourbaki [1], Book VI, Chapter 6, §3, Theorem 1.
22.33 Theorem (Disintegration). Let $X$ and $Y$ be compact metric spaces, and let $\mu$ be a finite regular Borel measure on $X \times Y$. Let $\mu_1$ be the marginal measure on $X$ given by $\mu_1(A) = \mu(A \times Y)$. There is a Borel map $x \mapsto \mu^x$ of $X$ into the regular probability measures on $Y$ such that

$$\mu(S) = \int_X (\int_Y \chi_S(x,y) d\mu^x(y)) d\mu_1(x) .$$

Sketch of proof. Define a linear map $T$ from $L^1(\mu_1)$ into $C(X \times Y)^*$ by

$$(Tf)(g) = \int g \circ \pi_1 d\mu$$

where $\pi_1$ is the first coordinate projection. One has

$$\|Tf\| = \|f \circ \pi_1 d\mu\| = \int |f \circ \pi_1| d\mu = \int |f| d\mu_1 = \|f\| .$$

So by the Dunford-Pettis Theorem, there is a Borel map $B$ of $X$ into $C(X \times Y)^* = M(X \times Y)$ such that

$$(Tf)(g) = \int <B(x),g> f(x) d\mu_1(x) .$$

Now $B(t)$ is integration with respect to a measure $\nu^t$ on $X \times Y$, so we obtain

$$\int g(x,y) f(x) d\mu = \int \int g(x,y) d\nu^t(x,y) f(t) d\mu_1(t) .$$

If $f$ and $g$ are positive, the left hand side is positive, hence $\int g d\nu^t \geq 0 (a.e.d\mu)$. Whence $\nu^t \geq 0 (a.e.d\mu_1)$. Similarly, one obtains $\|\nu^t\| \leq 1 (a.e.d\mu_1)$.

Let $D$ be a disc of positive radius $\epsilon$ on $X$. If $f$ has support in $D$ and $g$ vanishes on $\pi_1^{-1}(D)$, then

$$0 = \int (\int g(x,y) d\nu^t(x,y)) f(t) d\mu_1(t) .$$

Hence $\int g(x,y) d\nu^t(x,y) = 0$ for almost all $t$ in $D$. Since $C(X \times Y)$ is separable, choose a dense set $g_n$ in $\{g: \pi_1^{-1}(D) = 0\}$. Then one obtains a set $N$ of measure zero so that $\text{supp}(\nu^t) \subseteq \pi_1^{-1}(D)$ for $t \in D \setminus N$. Utilize a countable collection of discs $D_n$ with the property that for any $\epsilon$, $\{D_n: \text{diam}(D_n) < \epsilon\}$ covers $X$ to deduce that $\text{supp}(\nu^t) \subseteq \pi_1^{-1}(t) (a.e.d\mu_1)$. Thus there is a measure $\mu^t$ on $Y$ such that $\int g d\nu^t = \int g(t,y) d\mu^t(y)$. Hence, one has

$$\int g(x,y) f(x) d\mu = \int \int g(x,y) d\mu^t(y) f(x) d\mu_1(x)$$

for all $g$ in $C(X \times Y)$. This extends to all bounded Borel functions by Egoroff’s Theorem and the Lebesgue Dominated Convergence Theorem. Uniqueness is easy.
22.34 Corollary. Let \( X \) be a compact metric space with a finite regular Borel measure \( m \). Let \( \mu \) belong to \( A(X,m) \). Then there is a Borel map \( x \rightarrow \mu^x \) from \( X \) into the regular Borel measures on \( X \) such that

\[
\mu(S) = \int \left( \int \chi_S(x,y) d\mu^x(y) \right) dm(x)
\]

and \( \text{ess.sup} \| \mu^x \| \leq \| \mu \| \).

Sketch of proof. Apply the theorem to \( |\mu| \). Then by the Radon-Nikodym Theorem, there are bounded Borel functions so that \( d\mu = h d|\mu| \) and \( d|\mu| = kdm \). Putting these together yields the corollary.

22.35 Corollary. \( (T_\mu f)(x) = \int f(y) d\mu^x(y) \) \((a.e.m)\).

Proof.

\[
\int T_\mu f(x) \overline{g(x)} dm(x) = (T_\mu f, g) = \int \int f(y) \overline{g(x)} d\mu(y) dm(x)
\]

\[
= \int (\int f(y) d\mu^x(y)) \overline{g(x)} dm(x)
\]

This holds for all \( g \) in \( L^2(m) \), whence the result.

Naturally, one also deduces the existence of a Borel map \( y \rightarrow \mu_y \) such that

\[
\mu(S) = \int \left( \int \chi_S(x,y) d\mu_y(x) \right) dm(y)
\]

and

\[
(T_{\mu}^* g)(y) = \int g(x) d\overline{\mu}(x) \quad (a.e.m)
\]

where \( \overline{\mu}(A) = \mu(A) \) is the conjugate of \( \mu \).

22.36 Theorem. For \( \mu, \nu \) in \( A(X,m) \), the measure \( \mu * \nu \) given by

\[
\mu * \nu(S) = \int (\mu_x \times \nu^y)(S) dm(x)
\]

belongs to \( A(X,m) \), and \( T_\mu T_\nu = T_{\mu * \nu} \).

Proof. Since \( \| \mu^x \| \leq \| \mu \| \) and \( \| \nu^y \| \leq \| \nu \| \), \( \mu * \nu \) is a finite Borel measure. Moreover

\[
(\mu * \nu)(A) = (\mu * \nu)(A \times X) = \int \mu_x(A) \| \nu^y \| dm(x)
\]

\[
\leq \| \nu \| \mu_1(A) \leq \| \nu \| \| \mu \| m(A)
\]

Similarly, \( (\mu * \nu)_2 \leq \| \mu \| \| \nu \| m \). So \( \| \mu * \nu \| \leq \| \mu \| \| \nu \| \), and \( \mu * \nu \) belongs to \( A(X,m) \). For \( f, g \) in \( L^2(m) \),

\[
(T_\mu T_\nu f, g) = (T_\nu f, T_\mu^* g) = \int \int f(y) \overline{g(x)} \mu^x dm(x)
\]

\[
= \int \int \left( \int f(y) \overline{g(x)} \mu_y dm(y) \right) dm(x)
\]

\[
= \int \int f(y) \overline{g(x)} \mu^x \mu_y dm(x) dm(y)
\]

\[
= \int f(y) \overline{g(x)} dm \mu * \nu = (T_{\mu * \nu} f, g)
\]

22.37 Corollary. \( A_{\text{min}}(X, m, \leq) \) is the weak* closure of 
\[
\{ T_\mu : \mu \in A(X, m), \text{supp}(\mu) \subseteq G(\leq) \}.
\]

Proof. It suffices to show that if \( \mu, \nu \) have support in \( G \), so does \( \mu \ast \nu \). For then, \( \{ T_\mu : \text{supp}(\mu) \subseteq G \} \) is closed under multiplication, and thus so is its weak* closure. We claim that \( \mu_\# \) is supported in \( \{ x : x \geq y \} \) \((a.e.m)\) and \( \nu^\# \) is supported on \( \{ y : x \geq y \} \) \((a.e.m)\). For
\[
0 = \int_{G^2} f d\mu = \int (\int x^i : x \geq y) f(x, y) d\mu_y(x) dm(y)
\]
for all \( f \) in \( C(X \times Y) \). Hence \( x^i : x \geq y \) \( d\mu_x = 0 \) \((a.e.m)\) as claimed. The same holds for \( \nu^\# \). Thus, \( \mu_\# \ast \nu^\# \) is supported on \( \{(y, x) : y \geq x \geq z\} \) which is contained in \( G \) for almost all \( x \). Consequently, \( \mu \ast \nu \) supported in \( G \) as desired. \( \blacksquare \)

Notes and Remarks.

The entire content of this chapter is contained in Arveson's seminal paper \([6]\). A shorter proof on reflexivity (Corollary 22.10) valid for non-separable spaces as well is contained in Davidson \([1]\). It avoids the use of pseudo-integral operators, but does not yield the full strength of Theorem 22.9. This argument is outlines in the Exercises.

Arveson constructs a CSL \( L \) which is not synthetic based on failure of spectral synthesis in \( R^3 \). Froelich \([1]\) makes the connection even more explicit. Let \( G \) be a locally compact abelian group. The maximal ideal space of \( L^1(G) \) is naturally homeomorphic to the dual group \( \hat{G} \), and the Gelfand map is the Fourier transform. Given a closed subset \( E \) of \( \hat{G} \), form two ideals in \( L^1(G) \). Let
\[
k(E) = \{ f \in L^1(G) : \hat{f} \mid E = 0 \}
\]
and
\[
I(E) = \{ f \in L^1(G) : E \subseteq \text{int} \hat{f}^{-1}(0) \}
\]
(i.e. the functions \( f \) such that \( \hat{f} \) vanishes on \( E \), or in a neighbourhood of \( E \), respectively). A set \( E \) satisfies spectral synthesis if \( I(E) \) is dense in \( k(E) \).

L. Schwartz showed that \( S^{n-1} \) is not a set of spectral synthesis in \( R^n \) for \( n \geq 3 \). It is this example that Arveson uses to construct his example. Malliavin constructed Cantor sets in any nondiscrete locally compact abelian group which fail to admit spectral synthesis. This is a difficult area of harmonic analysis, and a characterization of sets with spectral synthesis would seem to be well beyond present day capability.

Let \( E \) be a closed subset of a LCA group \( \hat{G} \). Form the algebra \( A_E \) of all operators of the form
\[
\begin{bmatrix}
M_1 & T_\mu \\
0 & M_2
\end{bmatrix}
\]
where \( M_i \) belong to \( L^S(G) \), and \( \mu \)
is a measure in $A(G,m)$ supported on $\{(x,y) : x - y \in E\}$. Let $L_E = \text{Lat } A_E$. Clearly, $L_E$ is a CSL and $A_E = A_{\text{min}}(L_E)$.

**Theorem (Froelich [1]).** $L_E$ is synthetic if and only if $E$ is a set of spectral synthesis in $G$.

Froelich also translates other peculiar phenomena in harmonic analysis to produce CSL algebras with interesting properties. For example, he constructs algebras which contain operators in $C_p$ for $p > 2$, but not $C_2$ operators; and an algebra which contains compact operators but no operators in any $C_p$ class. See the end of Chapter 23.

Arveson's paper also contains a section devoted to lattice theoretic invariants of commutative subspace lattices. He uses this to distinguish lattices in some special classes.

**Exercises.**

22.1 (Davidson) Let $L$ be a finite CSL with atoms $A_i$, $1 \leq i \leq n$. Let $\preceq$ be the partial order on the atoms induced from $L$. Show that $\text{Lat}(\text{Alg}(L) \otimes \mathcal{C}l)$ consists of the ranges of

$$\{P = \sum_{i=1}^{n} P(A_i) \otimes P_i : A_i \preceq A_j \text{ implies } P_i \leq P_j\}.$$

22.2 (Davidson) Let $L$ be a finite CSL. Let $R = u \otimes v^*$ be a rank one operator with $\|u\| = \|v\| = 1$. Let $d = \text{dist}(R, \text{Alg} L)$ and $\beta = \sup_{L \in L} \|P(L) P(L)^*\|$. Let $P_\perp$ be the projection onto $\mathbb{C}v$. Define $t \geq 0$ and a unit vector $y$ by $(P_\perp \otimes I)P_\perp = t(v \otimes y)$. Prove that

$$d \leq \|P(L) u \otimes y\| \|P(L) v \otimes y\|.$$

(c) Let $a_i, b_i, t_i$ belong to $[0,1]$, $1 \leq i \leq n$ such that $\sum_{i=1}^{n} t_i = 1$ and $a_i b_i \leq \gamma$. Show that

$$\left(\sum_{i=1}^{n} t_i a_i\right) \left(\sum_{j=1}^{n} t_j b_j\right) \leq (1 + \gamma^2)/2.$$

(d) Apply (a), (b) and (c) to obtain $d^2 \leq (1 + \beta^2)/2$.

22.3 (Davidson) Let $L$ be a CSL and let $M_k$ be the $k \times k$ matrices.

(a) Show that $\text{Alg}(L \otimes \mathcal{C}^k) = \text{Alg}(L) \otimes M_k$ and $\text{Lat}(\text{Alg}(L) \otimes M_k) = K \otimes \mathcal{C}^k$.

(b) Since $L$ is closed in the strong operator topology, show that if $P$ is any projection in $L'$ not in $L$, then there are unit vectors $x, y$ in $\mathcal{H} \otimes \mathcal{C}^k$ (for some $k$) such that $(P \otimes I_k)x = x$ and
\[(P^\perp \otimes I_k)y = y \text{ and } \sup_{L \in L \otimes \mathcal{H}} \|P(L)^\perp y\| \cdot \|P(L)z\| < 1.\]

(c) Suppose \(P\) belongs to \(\text{Lat}(\text{Alg}(L))\) but is not in \(L\). Use (b) to construct a CSL \(L_1\) and a projection \(P_1\) in \(\text{Lat}(\text{Alg}(L_1))\) and a rank one operator \(R\) such that \(\text{dist}(R, \text{Alg}(L_1)) = 1\) but \(\sup_{L \in L_1} \|P(L)^\perp RP(L)\| < 1\).

22.4 (Davidson) Let \(L\) be a CSL and let \(\mathcal{F}\) denote an arbitrary finite sublattice of \(L\).

(a) For \(T\) in \(B(\mathcal{H})\), \(\text{dist}(T, \text{Alg} L) = \sup_{\mathcal{F} \subseteq L} \text{dist}(T, \text{Alg} \mathcal{F})\).

(b) Use Exercises 22.2 and 22.3 to show that every CSL is reflexive.
23. Complete Distributivity and Compact Operators

In this chapter, we explore the relationship of compact operators in $\text{Alg}(L)$ to the lattice structure of $L$. The main theorem is the equivalence of complete distributivity of $L$ and the weak* density of the finite rank operators in $\text{Alg}(L)$.

An abstract lattice $L$ is distributive if

\[ x \lor (y \land z) = (x \lor y) \land (x \lor z) \text{ for all } x, y, z \text{ in } L \quad (D) \]
\[ x \land (y \lor z) = (x \land y) \lor (x \land z) \text{ for all } x, y, z \text{ in } L \quad (D^*) \]

The two distributive laws $(D)$ and $(D^*)$ are equivalent (Exercise 23.1) so only one need be checked. If $L$ is a CSL, then the identities

\[ P(L \land M) = P(L)P(M) \]
\[ P(L \lor M) = P(L)+P(M)-P(L)P(M) \]

readily yield both $(D)$ and $(D^*)$.

A complete lattice $L$ is completely distributive if it has a distributive law for arbitrary sets. Let $\{\Phi_\lambda : \lambda \in \Lambda\}$ be a collection of subsets of $L$, and let $\Pi \Phi_\lambda$ denote the collection of functions $F : \Lambda \rightarrow \bigcup \Phi_\lambda$ such that $F(\lambda) \in \Phi_\lambda$. The distributive laws becomes

\[ \bigwedge_{\lambda \in \Lambda} (\bigvee F(\lambda)) = \bigvee_{F \in \Pi \Phi_\lambda} \left( \bigwedge_{\lambda \in \Lambda} F(\lambda) \right) \text{ for all } \{\Phi_\lambda \subseteq L : \lambda \in \Lambda\} \quad (\text{CD}) \]
\[ \bigvee_{\lambda \in \Lambda} (\bigwedge F(\lambda)) = \bigwedge_{F \in \Pi \Phi_\lambda} \left( \bigvee_{\lambda \in \Lambda} F(\lambda) \right) \text{ for all } \{\Phi_\lambda \subseteq L : \lambda \in \Lambda\} \quad (\text{CD}^*) \]

A complete lattice is completely distributive if both (CD) and (CD*) hold.

The reader can easily verify that every complete sublattice of the lattice of subsets of a set is completely distributive. On the other hand, the Boolean algebra of idempotents in $L^\infty(m)$ for a non-atomic measure $m$ is not completely distributive. To see this, consider $L^\infty(0,1)$. Identify each $x$ in $(0,1)$ by its binary expansion $x = \epsilon_1 \epsilon_2 \ldots$ (which is a uniquely determined a.e.m.). Set $L_n = \{x : \epsilon_n = 0\}$, and let $\Lambda$ consist of all infinite subsets $S$ of $\mathbb{N}$. It is easy to verify that $\bigwedge_{n \in S} L_n = 0$ and $\bigvee_{n \in S} L_n = 1$. Thus

\[ \bigwedge_{\lambda \in \Lambda} \left( \bigvee_{n \in S} L_n \right) = 1. \]

But the range of any function $F$ in $\prod S$ has infinite range, so
\[ \bigvee_{F \in \mathcal{I} \subseteq S} \left( \bigwedge_{z \in A} L_F(z) \right) = 0 . \]

So \( L^\infty(0,1) \) is not completely distributive.

Let \( L \) be a complete lattice. A semi-ideal of \( L \) is a subset \( M \) of \( L \) which is decreasing (i.e. \( x \in M \) and \( y \leq x \) implies \( y \in M \)). For \( x \) in \( L \), let

\[ \phi(x) = \{ \text{semi-ideals } M \text{ of } L : x \leq \bigvee M \} . \]

Define \( K(x) = \bigcap \phi(x) \). Also, define

\[ x_\# = \bigvee \{ y \in L : x \leq y \} \quad \text{and} \quad x_\& = \bigvee \{ y : x \leq y \} . \]

**23.1 Lemma.** For any lattice \( L \), \( K(x) = \{0\} \cup \{ y \in L : x \leq y \} \).

Hence

\[ x_\# = \bigvee K(x) \leq x . \]

**Proof.** For each \( y \) in \( L \), \( \{ z : y \leq z \} \) is a semi-ideal which does not contain \( y \). If \( y \neq 0 \) belongs to \( K(x) \), then \( y \) belongs to every semi-ideal \( M \) with \( \bigvee M \geq x \). Hence \( y_\& = \bigvee \{ z : y \leq z \} \leq x \). Conversely, if \( x \leq y_\& \), suppose that \( M \) is an order ideal such that \( x \leq \bigvee M \). Then \( M \) is not contained in \( \{ z : y \leq z \} \). So \( M \) contains some \( z \geq y \) and hence contains \( y \). But \( M \) was arbitrary, so \( y \) belongs to \( K(x) \). Since \( M = \{ y \in L : y \leq x \} \) is a semi-ideal with \( \bigvee M = x \), \( x_\# = \bigvee K(x) \leq \bigvee M = x \).

**23.2 Theorem.** For a complete lattice \( L \), the following are equivalent:

(i) \( L \) is completely distributive.

(ii) \( L \) satisfies (CD).

(ii*) \( L \) satisfies (CD*).

(iii) \( L \) is a complete homomorphic image of a complete lattice of subsets.

(iv) \( L \) has the splitting property: If \( x, y \in L \) and \( x \leq y \), then there exist \( p, q \in L \) with \( p \leq y \) and \( x \leq q \) such that

\[ \{ z : z \geq p \} \cup \{ z : z \leq q \} = L . \]

(v) \( x = x_\# \) for every \( x \in L \).

**Proof.** Since (CD) and (CD*) are preserved by a complete lattice homomorphism, it follows that (iii) implies (i). Clearly, (i) implies (ii) and (ii*). For any complete lattice \( L \), let \( S(L) \) denote the collection of all semi-ideals of \( L \). Then \( S(L) \) forms a complete lattice of subsets of \( L \) under intersection and union. Define a map \( \theta \) from \( S(L) \) into \( L \) by

\[ \theta(M) = \bigvee M . \]

The map \( \theta \) is onto since \( \theta \{ y \in L : y \leq x \} = x \). This map preserves arbitrary joins because
\[ \theta(\bigcup_{\lambda \in \Lambda} M_{\lambda}) = \bigvee_{\lambda \in \Lambda} \theta(\bigvee_{\lambda \in \Lambda} M_{\lambda}) = \bigwedge_{\lambda \in \Lambda} (\bigvee_{\lambda \in \Lambda} M_{\lambda}) = \bigwedge_{\lambda \in \Lambda} \theta(M_{\lambda}). \]

Now consider \( \bigcap_{\lambda \in \Lambda} M_{\lambda} \). This will be shown to equal \( \{ \bigwedge_{\lambda \in \Lambda} F(\lambda) : F \in \Pi M_{\lambda} \} \).

Clearly, \( \bigwedge_{\lambda \in \Lambda} F(\lambda) \leq F(\lambda) \in M_{\lambda} \) for each \( M_{\lambda} \); and hence belongs to \( \bigcap_{\lambda \in \Lambda} M_{\lambda} \). On the other hand, if \( x \) belongs to \( \bigcap_{\lambda \in \Lambda} M_{\lambda} \), then \( F(\lambda) = x \) for all \( \lambda \) has \( \bigwedge F(\lambda) = x \). Now suppose that \( L \) has (CD). Then

\[ \theta(\bigcap_{\lambda \in \Lambda} M_{\lambda}) = \bigvee_{F \in \Pi M_{\lambda}} (\bigwedge_{\lambda \in \Lambda} F(\lambda)) = \bigwedge_{\lambda \in \Lambda} (\bigvee_{\lambda \in \Lambda} M_{\lambda}) = \bigwedge_{\lambda \in \Lambda} \theta(M_{\lambda}). \]

Hence \( \theta \) is a complete lattice isomorphism of \( S(L) \) onto \( L \). So (ii) implies (iii). Consequently, (ii) implies (ii*). These two notions are dual, so interchanging the role of meet and join shows that (ii*) implies (ii) as well.

Now consider (iii) \( \Rightarrow \) (iv). If \( L \) is a complete lattice of subsets, and \( A \) and \( B \) are sets in \( L \) with \( A \subseteq B \), let \( a \) be any element of \( A \setminus B \). Let \( P \) be the least element of \( L \) containing \( a \), and let \( Q \) be the largest element of \( L \) not containing \( a \). Clearly, \( P \subseteq B \) and \( A \subseteq Q \). If \( C \) belongs to \( L \), either \( a \in C \), whence \( P \subseteq C \) or \( a \notin C \), whence \( C \subseteq Q \). So \( L \) has the splitting property.

Now suppose \( L \) is a complete homomorphic image \( \phi(M) \) of a complete lattice \( M \) of sets. If \( x, y \) belong to \( L \) and \( x \leq y \), let \( A = \bigcap \phi^{-1}(x) \) and \( B = \bigcup \phi^{-1}(y) \). So \( \phi(A) = x \) and \( \phi(B) = y \), and \( A(B) \) is minimal (maximal) with this property. Let \( P \) and \( Q \) be obtained in \( M \) as above. Let \( p = \phi(P) \) and \( q = \phi(Q) \). Since \( \phi \) is surjective, \( L \) equals the union \( \{ z : z \geq p \} \cup \{ z : z \leq q \} \). Suppose \( p \leq y \). Then \( \phi(P \cup B) = p \cup y = y \). By the maximality of \( B \), one has \( P \subseteq B \) contrary to fact. So \( p \nleq y \). Similarly \( q \nleq x \). Thus (iii) implies (iv).

Assume (iv) holds. If \( x \neq x_{\#} \) for some \( x \) in \( L \), then \( x_{\#} \leq x \) by Lemma 23.1. So \( x \nleq x_{\#} \). By the splitting property, there exist \( p, q \) in \( L \) with \( p \nleq x_{\#} \) and \( q \nleq x \) such that \( \{ y : y \geq p \} \cup \{ y : y \leq q \} = L \). Thus

\[ p = \bigvee \{ y : y \geq p \} \leq \bigvee \{ y : y \leq q \} = q \leq x . \]

As \( p \nleq x \) it follows from the definitions that \( p \leq x_{\#} \). This contradiction establishes (v).

Now suppose (v) holds. Define the map \( \theta \) as in the first paragraph. It suffices to show that \( \theta \) preserves meets. Given a set of semi-ideals \( \{ M_{\lambda} : \lambda \in \Lambda \} \), let \( x = \bigwedge_{\lambda \in \Lambda} \theta(M_{\lambda}) \). Then each \( M_{\lambda} \) belongs to \( \phi(x) \). Hence
\[ x = \bigwedge_{\lambda \in \Lambda} \theta(M_{\lambda}) \geq \bigwedge_{M \in \varnothing(x)} \theta(M) \]
\[ \geq \theta\left( \bigcap_{M \in \varnothing(x)} M \right) = \theta(K(x)) = x_{\#} = x . \]

Thus
\[ x = \bigwedge_{\lambda \in \Lambda} \theta(M_{\lambda}) \geq \theta\left( \bigcap_{\lambda \in \Lambda} M_{\lambda} \right) \geq \theta(K(x)) = x . \]

So \( \theta \) preserves meets, establishing (iii).

Now, consider subspace lattices again. First, we obtain an easy generalization of Lemma 3.7.

23.3 Lemma. Let \( L \) be a subspace lattice. A rank one operator \( x \otimes y^* \) belongs to \( \text{Alg}(L) \) if and only if there is an \( L \) in \( L \) such that \( x \in L \) and \( y \in (L_{-})^{\perp} \).

Proof. Suppose \( x \otimes y^* \) belongs to \( \text{Alg}(L) \), and let \( L \) be the least element of \( L \) containing \( x \). If \( M \) belongs to \( L \) and is not orthogonal to \( y \), then,
\[ x \in x \otimes y^*(M) \subseteq M , \]
hence \( M \geq L \). Consequently, \( L_{-} = \bigvee \{ M \in L : M \not\leq L \} \) is orthogonal to \( y \).

Conversely, if \( x \in L \) and \( y \in (L_{-})^{\perp} \), then for each \( M \) in \( L \), either i) \( M \geq L \) whence \( x \otimes y^*(M) \subseteq L \subseteq M \), or ii) \( M \not\geq L \), whence \( M \leq L_{-} \) so \( x \otimes y^*(M) = \{ 0 \} \subseteq M \). Hence \( x \otimes y^* \) belongs to \( \text{Alg}(L) \).

Let \( R_{1}(L) \) denote the algebra generated by the rank one operators in \( \text{Alg}(L) \). Note that \( R_{1}(L) \) is a two sided ideal in \( \text{Alg}(L) \).

23.4 Lemma. For each vector \( u \) in \( H \), let \( L(u) \) denote the least element of \( L \) containing \( u \). Then \( \overline{R_{1}(L)u} = L(u)_{\#} \).

Proof. Let \( M \) belong to \( L \). If \( u \notin M_{-} \), then there is a vector \( y \) in \( (M_{-})^{\perp} \) such that \( (u,y) \neq 0 \). By Lemma 23.3, it then follows that \( R_{1}(L)u \) contains \( M \). Moreover, that lemma shows that these are the only vectors which are the image of \( u \) under a rank one operator in \( \text{Alg}(L) \). Thus
\[ \overline{R_{1}(L)u} = \bigvee \{ M : u \notin M_{-} \} \]
\[ = \bigvee \{ M : L(u) \not\leq M_{-} \} = L(u)_{\#} . \]
23.5 Corollary. Let $R_1(L)$ consists of $\{K : L_{\#} K \leq K \leq L \text{ for some } L \in L \}$. In particular, every completely distributive lattice is reflexive.

Proof. Let $K$ be invariant for $R_1(L)$, and let $L$ be the least element of $L$ containing $K$. Then since $L = \bigvee_{u \in K} L(u)$,

\[
K \supseteq \overline{R_1(L)K} = \bigvee_{u \in K} \overline{R_1(L)u} = \bigvee_{u \in K} L(u)_{\#} = \bigvee_{u \in K} \{M \in L : L(u) \leq M_{\#} \} = \{M \in L : L \leq M_{\#} \} = L_{\#}.
\]

Conversely, if $L_{\#} \leq K \leq L$, then $R_1(L)K \subseteq R_1(L) = L_{\#} \subseteq K$. If $L$ is completely distributive, then $L = L_{\#}$ so $Lat R_1(L) = L$.

23.6 Corollary. If $R_1(L)$ is weak* dense in $Alg(L)$, then $L$ is completely distributive.

Proof. By Lemma 23.4, $L_{\#} = \overline{R_1(L)L} = (Alg(L)L = L$. Thus by Theorem 23.2, $L$ is completely distributive.

Let $C_2(L)$ denote $C_2 \cap Alg(L)$, the Hilbert-Schmidt operators in $Alg(L)$.

23.7 Theorem. Let $L$ be a commutative subspace lattice. The following are equivalent.

i) $L$ is completely distributive.

ii) $R_1(L)$ is weak* dense in $Alg(L)$.

iii) $C_2(L)$ is dense in $Alg(L)$ in the weak operator topology.

iv) For every non-zero projection $P$ in $L'$, $PC_2(L)L = 0$.

v) For every non-zero projection $P$ in $L'$, $PR_1(L)L = 0$.

iv') If $L = L(X, \leq, m)$, then iv) can be replaced by: For every subset $A$ of $X$ with $m(A) > 0$, $m^2(A \times A \cap G(\leq)) > 0$.

Proof. i) $\Rightarrow$ ii). If $L$ is completely distributive, Lemma 23.4 shows that $\overline{R_1(L)u} = \overline{Alg(L)u}$ for every vector $u$ in $\mathcal{H}$. Since the weak* closure of $R_1(L)$, $\overline{R_1(L)}$, is an ideal of $Alg(L)$, it is an $Alg(L)$ bimodule. Thus by Theorem 22.18, $\overline{R_1(L)}$ contains $\mathcal{A}_{min}(L)$. In particular, it contains the identity operator. So it equals all of $Alg(L)$.

Clearly, ii) implies iii) implies iv). By Theorem 22.4, $L$ can be represented as $L(X, \leq, m)$. Since $L^\infty(X, m)$ is contained in $L'$, one obtains $P(A)C_2(L)L \neq 0$ whenever $P(A) \neq 0$ (i.e. $m(A) > 0$). So $A \times A \cap G(\leq)$ supports a Hilbert-Schmidt operator, and hence has positive $m^2$ measure. This established iv').
Suppose iv) holds, and fix a set $A$ with $m(A) > 0$. Then by Fubini’s Theorem,
\[ 0 < m^2(A \times A \cap G) = \int_A m\{x \in A : x \geq y\} dm(y). \]

Let $E_y = \{x : x \geq y\}$. Then $B = \{y \in A : m(A \cap E_y) > 0\}$ has positive measure. Likewise
\[ 0 < m^2(B \times B \cap G) = \int_B m\{y \in B : y \leq x\} dm(x). \]

Let $F_x = \{y : y \leq x\}$. Then $C = \{x \in B : m(F_x \cap B) > 0\}$ has positive measure. Choose any $x_0$ in $C$. Then $m(F_{x_0} \cap B) > 0$ and $m(A \cap E_{x_0}) > 0$. Hence
\[ (E_{x_0} \cap A) \times (F_{x_0} \cap B) = \{(x,y) : x \in A, y \in B \text{ and } x \geq x_0 \geq y\}. \]

Thus this rectangle is contained in $G(\leq)$, and hence $P(E_{x_0} \cap A) B (\mathcal{H})P(F_{x_0} \cap B)$ is contained in $\text{Alg}(L)$. Thus $P(A)R_1(L)P(A) \not= 0$. This proves v).

Now assume v) holds. For any $L$ in $L$, one has by Lemma 23.4, $(L-L\#)R_1(L)(L-L\#) = 0$. Hence $L = L\#$ for all $L$ in $L$. By Theorem 23.2, $L$ is completely distributive.

A simple reworking of the proof above yields:

23.8 Proposition. Let $L$ be a commutative subspace lattice. Then $\mathcal{K} \cap \text{Alg}(L)$ is weak$^*$ dense in $\text{Alg}(L)$ if and only if $P(\mathcal{K} \cap \text{Alg}(L))P \not= 0$ for every non-zero projection $P$ in $L$.

Proof. The “only if” direction is obvious. Conversely, the weak$^*$ closure $\mathcal{A}$ of $\mathcal{K} \cap \text{Alg}(L)$ is an ideal in $\text{Alg}(L)$ and hence a bimodule. If $x$ belongs to $\mathcal{K}$, and $L = \text{Alg}(L)x$ and $M = \mathcal{K}x$, one sets $P = P(L)xP(M)$. Then $P(\mathcal{K} \cap \text{Alg}(L))P = 0$ and thus $P = 0$. By Theorem 22.18, $\mathcal{A}$ contains $\mathcal{A}_{\text{min}}(L)$ including the identity. Since $\mathcal{A}$ is an ideal, $\mathcal{A} = \text{Alg}(L)$.

23.9 Corollary. Every completely distributive CSL is synthetic.

Proof. Immediate from Theorem 23.7 and Lemma 22.20.

There is a simple application of complete distributivity to tensor products of CSL algebras. As in Section 15.A, let $\text{Alg} L_1 \otimes \text{Alg} L_2$ denote the WOT closed span of the elementary tensors $A \otimes B$ acting on $\mathcal{H}_1 \otimes \mathcal{H}_2$. Similarly, let $L_1 \otimes L_2$ denote the complete lattice generated by $\{L_1 \otimes L_2 : L_1 \in L_1, L_2 \in L_2\}$.
23.10 Corollary. Let \( L_1 \) be a completely distributive CSL, and let \( L_2 \) be any complete subspace lattice. Then

\[
\text{Alg} L_1 \otimes \text{Alg} L_2 = \text{Alg}(L_1 \otimes L_2)
\]

If \( L_2 \) is a CSL as well, then

\[
\text{Lat}(\text{Alg} L_1 \otimes \text{Alg} L_2) = L_1 \otimes L_2.
\]

Proof. Since \( A \otimes B \) leaves each \( L_1 \otimes L_2 \) invariant, one always has

\[
\text{Alg} L_1 \otimes \text{Alg} L_2 \subseteq \text{Alg}(L_1 \otimes L_2)
\]

By Theorem 23.7, \( R_1(L) \) is weak* dense in \( \text{Alg}(L) \). By Exercise 11.4, it follows that the unit ball of \( R_1(L) \) is strong* dense in the ball of \( \text{Alg}(L) \). Let \( R_n \) be a sequence of contractions in \( R_1(L) \) converging strong* to \( I \).

Let \( S_{n,j} \) be rank one operators in \( R_1(L) \) such that \( R_n = \sum_{j=1}^{m_n} S_{n,j} \). Let us write \( S_{n,j} = x_{n,j} y_{n,j}^* \) (suppressing the \( \otimes \) which plays two roles here). Fix any operator \( T \) in \( \text{Alg}(L_1 \otimes L_2) \). Then \( (S_{n,j} \otimes I)T(S_{n,j} \otimes I) \) has the form \( x_{n,i} y_{n,i}^* \otimes B_{ij}^{(n)} \) for some \( B_{ij}^{(n)} \) in \( B(\mathcal{H}_2) \). Moreover, since this belongs to \( \text{Alg}(L_1 \otimes L_2) \), \( B_{ij}^{(n)} \) belongs to \( \text{Alg}(L_2) \). Further, if \( B_{ij}^{(n)} \neq 0 \), then \( x_{n,i} y_{n,i}^* \) belongs to \( \text{Alg}(L_1) \). Thus

\[
(R_n \otimes I)T(R_n \otimes I) = \sum_{i=1}^{m_n} \sum_{j=1}^{m_n} (S_{n,i} \otimes I)T(S_{n,j} \otimes I)
\]

belongs to \( \text{Alg}(L_1) \otimes \text{Alg}(L_2) \). This sequence converges to \( T \) in the weak* topology, and thus \( T \) belongs to \( \text{Alg}(L_1) \otimes \text{Alg}(L_2) \). So equality holds.

If \( L_2 \) is also a CSL, then by Theorem 22.11,

\[
L_1 \otimes L_2 = \text{Lat}(\text{Alg}(L_1 \otimes L_2)) = \text{Lat}(\text{Alg}(L_1) \otimes \text{Alg}(L_2))
\]

Finally, we introduce one more lattice theoretic property with connections to CSL lattices. By Exercise 23.4, every CSL lattice is infinitely distributive. Say that a complete, infinitely distributive lattice is \( \Lambda \)-distributive if for every subset \( \{L_n \mid n \in \mathbb{N}\} \) of \( L \), \( \Lambda = \{S \subseteq \mathbb{N} : |S| = \infty\} \), one has

\[
\bigvee_{S \in \Lambda} \left( \bigwedge_{n \in S} L_n \right) = \bigvee_{F \in \Pi S} \left( \bigwedge_{S \in \Lambda} L_F(S) \right)
\]

If \( L \) fails to be \( \Lambda \)-distributive, then the left hand side, say \( F \), is strictly greater than the right hand side, \( E \). Let \( M_n = (L_n \vee E) \wedge F \). Then it is easy to verify that for every infinite subset \( S \) of \( \mathbb{N} \),

\[
\bigvee_{n \in S} M_n = F \quad \text{and} \quad \bigwedge_{n \in S} M_n = E.
\]

Conversely, the existence of such \( M_n \) contradicts \( W \)-distributivity because

\[
L \left( \bigvee_{S \in \Lambda} L_n \right) = F, \quad \text{while every function } F \in \Pi S \text{ has infinite range so}
\]

\[
\bigwedge_{S \in \Lambda} L_F(S) = E.
\]
\[ \bigvee_{F \in \Pi S} \left( \bigwedge_{S \in A} L_{P(S)} \right) = \bigvee E = E. \]

As we saw at the beginning of this chapter, the projection lattice of \( L^\infty(0,1) \) is not \( \Lambda \)-distributive.

23.11 Lemma. Suppose \( E, F, P_n, n \geq 1 \) are commuting projections such that \( E \leq P_n \leq F \) for all \( n \geq 1 \), and \( w-\lim P_n = Q \) exists in the weak operator topology. Then the following are equivalent.

1) \( E = P(\ker (I-Q)) \) and \( F = P(\text{Ran}(Q)) \).

2) For every infinite set \( S \) of positive integers, \( \bigvee_{n \in S} P_n = F \) and \( \bigwedge_{n \in S} P_n = E \).

Proof. Assume 1) holds, and fix a set \( S \). Then \( \bigwedge_{n \in S} P_n \geq E \) is the projection onto \( \{ x : P_n x = x \text{ for } n \in S \} \). Since \( \lim_{n \to \infty} (P_n x, x) = (Qx, x) \), this set is contained in \( \{ x : Qx = x \} = \ker (I-Q) \). Hence \( \bigwedge_{n \in S} P_n \leq E \) and equality follows. The identity \( F = \bigvee_{n \in S} P_n \) is similar.

Conversely, one has \( E \leq Q \leq F \) so
\[ E \leq P(\ker (I-Q)) \leq P(\text{Ran}(Q)) \leq F. \]

Suppose, \( P(\ker Q) \perp = P(\text{Ran } Q) < F \). Then there is a unit vector \( x \) such that \( Fx = x \) and \( Qx = 0 \). Thus \( \lim (P_n x, x) = 0 \) and \( (F x, x) = 1 \). Pick a subsequence \( S = \{ n_i, i \geq 1 \} \) with \( (P_{n_i} x, x) \leq 3^{-i} \). Then
\[ 1 = (Fx, x) = (\bigvee P_{n_i} x, x) \leq \sum_{i=1}^{\infty} (P_{n_i} x, x) \leq \frac{1}{2}. \]

This is contradictory, so \( F = P(\text{Ran } Q) \). Similarly, \( E = P(\ker (I-Q)) \). \( \text{■} \)

23.12 Theorem. Let \( L \) be a commutative subspace lattice. Then \( \{ P(L) : L \in L \} \) is compact on the strong operator topology if and only if \( L \) is \( \Lambda \)-distributive. In particular, this holds if \( K \cap \text{Alg}(L) \) is weak* dense in \( \text{Alg}(L) \).

Proof. Suppose \( L \) is not compact in the strong operator topology. Then since the unit ball of \( B (\mathcal{H}) \) is metrizable in the strong operator topology, there is a sequence \( P_n = P(L_n) \) with no strongly convergent subsequence. But the unit ball is WOT compact and metrizable, so we may assume that \( w-\lim P_n = Q \) exists. If \( Q \) were a projection, then this would converge strongly (Exercise 23.5). So \( Q \) is not a projection, whence \( E = P(\ker (I-Q)) < F = P(\text{Ran } Q) \).
It will be shown that \( \ker (I-Q) \) and \( \overline{\text{Ran}} Q \) both belong to \( L \). For if \( Qx = x \), then \( \lim_{n \to \infty} P_n x = x \) (as in Exercise 23.5), so for every \( T \) in \( \text{Alg}(L) \),

\[
T x = \lim_{n \to \infty} T P_n x = \lim_{n \to \infty} P_n T P_n x = w- \lim_{n \to \infty} P_n T x = Q T x .
\]

Hence \( T x \) belongs to \( \ker (I-Q) \). A similar computation shows that \( T^* \ker (Q) \) is contained in \( \ker Q \). As \( \overline{\text{Ran}} (Q) = \ker (Q)^\perp \), it is also invariant for \( \text{Alg}(L) \). So both subspaces belong to \( \text{Lat}(\text{Alg}(L)) = L \) by Corollary 22.10. Set

\[
Q_n = (P_n \lor E) \land F = E + P_n (F-E) .
\]

Clearly, \( Q_n \) belong to \( L \) and \( w- \lim Q_n = Q \). By Lemma 23.10, \( \lor_{n \in S} Q_n = F \) and \( \land_{n \in S} Q_n = E \) for every infinite subset \( S \) of \( \mathbb{N} \). By the remarks preceding the theorem, \( L \) is not \( \Lambda \)-distributive.

Conversely, suppose \( L \) is not \( \Lambda \)-distributive. Let \( Q_n \) and \( E < F \) be elements of \( L \) such that \( \lor_{n \in S} Q_n = F \) and \( \land_{n \in S} Q_n = E \) for every infinite subset \( S \) of \( \mathbb{N} \). This still holds if \( \{Q_n\} \) is replaced by a subsequence with a WOT limit \( Q \). By Lemma 23.11, \( \ker (I-Q) = E \mathcal{H} \) and \( \overline{\text{Ran}} (Q) = F \mathcal{H} \). So \( Q \) is not a projection. Hence \( L \) is not WOT closed, and thus is not compact in the strong operator topology.

Now if \( L \) is not compact, let \( E, F, Q, \) and \( Q_n \) be as above. Let \( K \) be any compact operator in \( \text{Alg}(L) \). For each \( x \) in \( \mathcal{H} \), \( w- \lim Q_n x = Q x \) whence \( \lim K Q_n x = K Q x \) in norm. Thus (as in the proof of the Aronszajn-Smith Theorem 3.1)

\[
K Q x = \lim_{n \to \infty} K Q_n x = \lim_{n \to \infty} Q_n K Q_n x \\
= \lim_{n \to \infty} Q_n K Q x = w- \lim_{n \to \infty} Q_n K Q x = Q K Q x .
\]

Consequently, \( K \) maps \( \overline{\text{Ran}} (Q) \) into \( \ker (I-Q) \). So

\[
(F-E)(K \cap \text{Alg}(L))(F-E) = \{0\} .
\]

By Proposition 23.8, \( K \cap \text{Alg}(L) \) is not weak* dense in \( \text{Alg}(L) \).

The proof above immediately yields the following corollary.

**23.13 Corollary.** If \( L \) is a CSL containing elements \( L_n \) such that \( \lor_{n \in S} L_n = \mathcal{H} \) and \( \land_{n \in S} L_n = \{0\} \) for every infinite subset \( S \) of \( \mathbb{N} \), then \( \text{Alg}(L) \) contains no non-zero compact operators.

**23.14 Example.** Let \( X = 2^\mathbb{N} \). For \( 0 < p < 1 \), let \( m_p \) be the measure on \( \{0, 1\} \) given by \( m_p (\{0\}) = p \) and \( m_p (\{1\}) = 1-p \). Let \( \mu_p \) be the infinite product of \( m_p \) on each copy of \( X \). Let \( \leq \) be the partial order
\((x_n) \leq (y_n)\) if and only if \(x_n \leq y_n\) for all \(n\). Then \(L = L(X, \leq, \mu_p)\) is the complete lattice generated by the subspaces \(L_k\) of functions supported on \(E_k = \{x_n: x_k = 0\}\). For any finite subset \(S\) of \(\mathbb{N}\),

\[
\mu_p\left(\bigcap_{k \in S} E_k\right) = p^{|S|} \quad \text{and} \quad \mu_p\left(\bigcup_{k \in S} E_k\right) = 1 - (1-p)^{|S|}.
\]

Thus it follows that if \(S\) is any infinite subset of \(\mathbb{N}\), then \(\bigwedge_{n \in S} L_n = 0\) and \(\bigvee_{n \in S} L_n = \mathcal{M}\). By Corollary 23.13, \(Alg(L) \cap K = \{0\}\).

Now, we consider briefly the implications of certain compact operators in \(Alg(L)\). Exercise 23.7 shows that, unlike the ne tools case, even rank two operators need not be a sum of rank one operators in \(Alg(L)\). However, the following theorem shows that finite rank operators in \(Alg(L)\) imply the existence of rank one operators. Exercise 23.8 shows that there may be Hilbert-Schmidt operators in \(Alg(L)\) but no finite rank operators.

**23.15 Lemma.** Let \(L\) be a CSL lattice. Suppose \(F\) is a rank \(n\) operator in \(Alg(L)\) such that \(PFQ\) has rank \(n\) or 0 for every pair of projections \(P, Q\) in \(L^{\oplus}\). Then \(F\) belongs to \(R_1(L)\).

**Proof.** Write \(F = \sum_{i=1}^n x_i \otimes y_i^*\), and let \(P, Q\) be projections in \(L^{\oplus}\). If \(0 \neq PFQ = \sum_{i=1}^n Px_i \otimes Qy_i^*\), then \(\{Px_i, 1 \leq i \leq n\}\) are linearly independent, as are \(\{Qy_i, 1 \leq i \leq n\}\). Let \(L\) be the least element of \(L\) containing \(x_1\), and hence all of \(\{x_i, 1 \leq i \leq n\}\). Suppose \(M\) belongs to \(L\) and \(M \notin L\). Then \(P(M)^{\perp} x_i \neq 0\) but \(0 = P(M)^{\perp} FP(M)\). Since \(\{P(M)^{\perp} x_i, 1 \leq i \leq n\}\) are independent, \(\{P(M)y_i, 1 \leq i \leq n\}\) are not independent and thus are all zero. So \(y_i\) belongs to \(M^{\perp}\), \(1 \leq i \leq n\). So each \(y_i\) belongs to \(\bigwedge (M^{\perp}: M \notin L) = (\bigvee (M: M \notin L))^{\perp} = (\mathcal{L}_{\infty})^{\perp}\).

Hence \(F = P(L)FP(L_{\infty})\). By Lemma 23.3, each \(x_i \otimes y_i^*\) belong to \(Alg(L)\). Consequently, \(F\) is a combination of \(n\) rank ones in \(Alg(L)\). \(\blacksquare\)

**23.16 Theorem.** Let \(L\) be a commutative subspace lattice. The norm closure of \(R_1(L)\) contains all finite rank operators in \(Alg(L)\).

**Proof.** Proceed by induction on \(n = \text{rank}(F)\). Clearly, if \(n = 1\), then \(F\) belongs to \(R_1(L)\). Suppose that every \(F\) of rank at most \(n-1\) belongs to \(R_1(L)\). Fix \(F\) in \(Alg(L)\) of rank \(n\). Let \(P_0\) be the supremum of all projections \(P\) in \(L^{\oplus}\) such that \(\text{rank}(PF) < n\), and let \(Q_0\) be the supremum of all projections \(Q\) in \(L^{\oplus}\) such that \(\text{rank}(P_0^{\perp} FQ) < n\). Choose pairwise orthogonal projections \(P_k\) and \(Q_k\) in \(L^{\oplus}\) such that \(\text{rank}(P_k F) < n\), \(\text{rank}(P_k^{\perp} FQ_k) < n\) and \(P_0 = \sum_{k \geq 1} P_k\) and \(Q_0 = \sum_{k \geq 1} Q_k\). By the induc-
tion hypothesis, each $P_\lambda F$ and $P_\lambda^\perp FQ_\lambda$ belongs to $\overline{R_1(L)}$. Since $F$ is compact,

$$F - P_\lambda^\perp FQ_\lambda = \lim_{m \to \infty} \sum_{k=1}^{m} P_k F + P_k^\perp FQ_k$$

belongs to $\overline{R_1(L)}$. Now $F_0 = P_0^\perp FQ_0^\perp$ has the property that either $PF_0Q = 0$ or $\text{rank}(PF_0Q) = n$. By Lemma 23.15, $F_0$ belongs to $R_1(L)$. Thus, $F$ belongs to $\overline{R_1(L)}$.

We conclude this chapter with some interesting examples of CSL algebras. The properties of the algebras will be deduced from some results of commutative harmonic analysis which will be stated without proof. Let $T$ denote the unit circle with Haar measure $m$. For any closed subset $E$ of $T$, let $G_E = \{ (z,w) \in T^2 : zw \in E \}$. Consider the $L^\infty(T)$ bimodule $A_E = A_{\max}(G_E)$ defined in section 22.28, and the associated CSL algebra $B_E$ consisting of all operators of the form

$$\begin{bmatrix} M_1 & A \\ 0 & M_2 \end{bmatrix}, \quad M_1, M_2 \in L^\infty(T), A \in A_E.$$ 

Since $L^\infty(T)$ is non-atomic, the compact operators in $B_E$ correspond to the compact operators in $A_E$. They are never dense in $B_E$.

Let $\mu$ be a finite regular (signed) Borel measure on $T$ (i.e. an element of $M(T) = C(T)^\ast$). Define a bounded operator in $L^2(T)$ by

$$C_\mu f(z) = f * \mu(z) = \int T f(zw) \mu(w) \, dw.$$ 

23.17 Lemma. Let $\mu$ be an element of $M(T)$ with closed support $E$. Then $C_\mu$ is a normal operator unitarily equivalent to $\text{diag}(\mu(n))_{n \in Z}$, and $\text{supp}(C_\mu) = G_E$.

Proof. Let $e_n = z^n, n \in Z$, be the standard basis for $L^2(T)$. Then

$$C_\mu e_n(z) = \int (zw)^n \mu(w) = \int w^n \mu(w) z^n = \mu(n) e_n(z).$$

For arbitrary $f, g$ in $L^2$,

$$(C_\mu f, g) = \int \int f(zw) \mu(w) \overline{g(z)} \, dm(z) = \int \int f(u) \overline{g(z)} \mu(zu) \, dm(z).$$

The measure $d \mu(zu) \, dm(z)$ has closed support $G_E$. Thus, if $f(u) \overline{g(z)}$ is supported on $U \times V$ disjoint from $G_E$, $(C_\mu f, g) = 0$ whence $\text{supp}(C_\mu)$ is contained in $G_E$. On the other hand, if $U \times V$ is open, and meets $G_E$, then $\chi_{U \times V} \, d \mu(zu) \, dm(z)$ is a non-zero measure, and thus does not annihilate all of $C(T \times T)$. Since $\text{span} \{ f(u) \overline{g(z)} : f, g \in C(T) \}$ is dense in $C(T \times T)$ by the Stone-Weierstrass Theorem, it follows that $P(U) C_\mu P(V) \neq 0$. So $\text{supp}(C_\mu) = G_E$. 

23.18 Theorem. Let $E$ be a closed subset of $T$. Let $J$ be any ideal of compact operators on $L^2$. If $A_E$ contains a compact operator in $J$, then there is a non-zero normal operator in $A_{E \cap J}$.

Proof. For $w$ in $T$, let $D_w$ denote the unitary operator $D_w f(z) = f(z \bar{w})$. (This operator is $C_{\delta_w}$ where $\delta_w$ is the point mass at $w$.) We claim that if $\text{supp}(A) \subseteq G_E$, then $\text{supp}(D_w A D_{\bar{w}}) \subseteq G_E$. Suppose that $U \times V$ is an open set, disjoint from $G_E$. Thus $U \cap (V E)$ is empty. Let $f$ be a function with support contained in $V$. Then $D_{\bar{w}} f$ has support contained in $V \bar{w}$. Thus $A D_{\bar{w}} f$ has support contained in $V E \bar{w}$, and $D_w A D_{\bar{w}} f$ has support in $V E$. This is disjoint from $U$, whence $U \times V$ is disjoint from $\text{supp}(D_w A D_{\bar{w}})$.

Let $M_z$ denote the multiplication operator by the identity function. Define

$$\Delta_n(A) = \int_T D_w M_z^n A D_{\bar{w}} dm(w).$$

This converges in the norm of the ideal $J$, so is an element of $A_{E \cap J}$. To see what this operator is explicitly, express $A$ as a matrix $(a_{nm})$ with respect to the basis $e_n$. The operator $D_w$ is diagonal with matrix $\text{diag}(w^n)$. Thus

$$(\Delta_0(A)e_n, e_m) = \int_T w^{n-m} a_{nm} dm(w) = \delta_{nm} a_{nm}. $$

That is, $\Delta_0(A)$ is the diagonal of $A$ with respect to the basis $e_n$. Since $M_z^n$ is just a shift by $n$ places in this basis, it follows that

$$\Delta_n(A) = \text{diag}(a_{k-h-n}).$$

Since $A$ is non-zero, at least one $\Delta_n(A) \neq 0$ as desired. \hfill \blacksquare

This diagonal operator may not be the Fourier series of a measure, so this may not be some $C_p$. In the terminology of harmonic analysis, this corresponds to a pseudo-measure. More precisely, the Fourier transform carries $l^1(Z)$ onto $A(T)$. The norm on $A(T)$ is precisely $\|f\|_A = \sum |f(n)| = \|\hat{f}(f)\|_1$. So the dual $PM(T) = A(T)^*$ is isometrically isomorphic to $\ell^\infty(Z)$. In this disguise, the functionals are called pseudo-measures.

23.19 Theorem (Salem [1]). There is a closed subset $E$ of $T$ of Lebesgue measure zero which supports a non-zero measure $\mu$ such that $\mu$ belongs to $\ell^p$ for all $p > 2$.

23.20 Corollary. There is a CSL algebra which contains no Hilbert-Schmidt operators, yet contains an operator $K$ belonging to $C_p$ for all $p > 2$. 

Proof. Let $E$ and $\mu$ be given by Salem's Theorem 23.19. Then

$$K = \begin{bmatrix}
0 & C_\mu \\
0 & 0
\end{bmatrix}$$

belongs to $\mathcal{B}_E$ by Lemma 23.17, and $K$ belongs to $\mathcal{C}_p$ for all $p > 2$. On the other hand, $m^2(G_E) = m(E) = 0$. So $\mathcal{A}_E$, and thus $\mathcal{B}_E$, contains no Hilbert-Schmidt operators.

23.21 Lemma. Let $A$ and $B$ be operators in $\mathcal{A}_E$ and $\mathcal{A}_F$ respectively. Then $AB$ belongs to $\mathcal{A}_{EF}$.

Proof. Let $V$ be an open subset of $\mathcal{T}$. Then $BP(V)$ has support contained in $VE$, and $AP(VE)$ has support contained in $VEF$. Thus,

$$ABP(V) = AP(VE)BP(V) = P(VEF)ABP(V).$$

Consequently, if $U \times V$ is disjoint from $G_{EF}$, then $U \cap VEF$ is empty and $P(U)ABP(V) = 0$.

The following result is taken from Graham and McGehee [1], Proposition 6.3.13.

23.22 Theorem. There is a closed subset $E$ of $\mathcal{T}$ such that $E^n = \{e_1e_2...e_n : e_i \in E\}$ has Lebesgue measure zero for all $n \geq 1$ which supports a non-zero measure $\mu$ such that $\mu(n)$ belongs to $c_0$.

23.23 Corollary. There is a CSL algebra which contains a non-zero compact operator, but contains no operators in $\mathcal{C}_p$ for any $p < \infty$.

Proof. Let $E$ and $\mu$ be given as in Theorem 23.22. By Lemma 23.17,

$$K = \begin{bmatrix}
0 & C_\mu \\
0 & 0
\end{bmatrix}$$

is a non-zero compact operator in $\mathcal{B}_E$. On the other hand, if $\mathcal{B}_E$ contains an operator in $\mathcal{C}_{2^n}$, it must have the form

$$\begin{bmatrix}
0 & A \\
0 & 0
\end{bmatrix}$$

where $A$ belongs to $\mathcal{A}_E \cap \mathcal{C}_{2^n}$. By Theorem 23.18, $\mathcal{A}_E \cap \mathcal{C}_{2^n}$ contains a non-zero normal operator $N$. Thus $N^n$ is a non-zero Hilbert-Schmidt operator. By Lemma 23.21, $N^n$ is supported on $G_{EF}$ which has Lebesgue measure zero. This is absurd. Hence $\mathcal{B}_E \cap \mathcal{C}_{2^n} = \{0\}$ for all $n \geq 1$.

Notes and Remarks.

The characterization Theorem 23.2 of complete distributivity is due to Raney [1, 2]. Lemmas 23.3-23.6 are due to Longstaff [2]. In Theorem 23.7, the equivalence of i), iii) and iv) is due to Hopenwasser, Laurie and Moore [1] while the equivalence of i), ii) and v) is due to Laurie and Longstaff [1]. Corollary 23.10 is due to Kraus [3]. Theorem 23.12 is in Wagner [3], which acknowledges joint work with Froelich and Moore. Froelich [2] had earlier proved Corollary 23.13 directly and gave Example
23.14. The question remains whether weak* density of $K$ in $Alg(L)$ or
even the strong compactness of $L$ is sufficient to imply complete distribu-
tivity. If not, what is the lattice condition corresponding to the weak* 
density of the compact operators in $Alg(L)$? Hopenwasser and Moore [1] 
show that the existence of finite rank operators in $Alg(L)$ implies 
$R_1(L) \neq 0$, and prove Theorem 23.16 in the finite width case without 
requiring the norm closure. The general result is new. The examples, 
23.17-23.23, are due to Frollech [1]. He also uses the existence of a set $E$
supporting pseudo-measures on $\ell^p$ for $p > q > 2$ but not for $p < q$ to pro-
duct CSL algebras with operators in $C^p$ for $p > q$ not $p < q$. A similar 
example gives a CSL with compact operators but no compact pseudo-
integral operators.

Exercises.

23.1  Let $L$ be a lattice satisfying the distributive law (D).

(i) Show that 
$(x \land y) \lor (x \land z) \lor (y \land z) = (x \lor y) \land (x \lor z) \land (y \lor z)$.

Hint: substitute $(x \land y) \lor (x \land z)$ for $x$ in (D).

(ii) Simplify (i) in the case $x \geq y$ to obtain the modular law

\[ x \geq y \text{ implies } x \land (y \lor z) = y \lor (x \land z) . \]  
(M)

(iii) Prove (D*). Hint: Apply $(x \lor y)$ to both sides of (i).

(iv) Show that (D), (D*), and (i) are equivalent.

23.2  (Longstaff) If $L$ is a complete lattice, define

\[ x_* = \land \{ y : y \in L, y \leq x \} . \]

(i) Prove that $x_\# \leq x_* \leq x \leq x_\#*$ for all $x$ in $L$.

(ii) Prove that $L$ is completely distributive if and only if $x = x_*$

for all $x$ in $L$.

23.3  (Raney)

(i) An element $x$ of a lattice $L$ is join-irreducible if for every sub-
set $M$ of $L$, $x \leq \lor M$ implies there exists $y \in M$, $x \leq y$. If $L$
is a complete lattice of subsets of a set $S$, for each $s$ in $S$, let 
\[ \ell(s) = \land \{ x : x \in L : s \in x \} . \] Show that $\ell(s)$ is join-irreducible.

(ii) Hence show that if $L$ is isomorphic to a complete lattice of 
subsets of $S$, then every element of $L$ is the joint of join-
irreducible elements.

(iii) Prove the converse of (ii).

(iv) Show that $[0,1]$ with the usual order is completely distributive,

but is not isomorphic to a complete lattice of subsets.
23.4 A complete distributive lattice $L$ is called meet continuous if

$$x \lor \left( \bigvee_{\lambda \in \Lambda} y_\lambda \right) = \bigvee_{\lambda \in \Lambda} (x \lor y_\lambda) \text{ for all } x, y_\lambda \text{ in } L$$

Show that every complete sublattice of the Boolean algebra of idempotents in $L^\infty(m)$ is meet and joint continuous for every measure $m$. Such lattices are called \textit{infinitely distributive}.

23.5 Suppose that a sequence $P_n$ of projections converges weakly to a projection $Q$. Prove that it converges strongly. Hint: Consider $\lim(P_n x, x)$ for $Qx = x$ and $Qx = 0$.

23.6 Show that if $K \cap Alg(L^\perp)$ is weak$^*$ dense in $Alg(L^\perp)$, then $Alg(L^\perp) + K$ is closed. Hint: Corollary 11.7.

23.7 (Hopenwasser-Moore) Let $D$ be the diagonal algebra with respect to an orthonormal basis $\{e_n, n \geq 1\}$. Let $A$ be the algebra on $H \oplus H$ consisting of all operators of the form

$$\begin{bmatrix} D_1 & T \\ 0 & D_2 \end{bmatrix}$$

where $D_i$ belong to $D$, $T$ belongs to $B(H)$, and $(T e_n, e_n) = 0$ for $n \geq 1$.

(i) Calculate $Lat A$.

(ii) Let $x = \sum_{n \geq 1} a_n e_n$ belong to $H$, and let $a_n \neq 0$ infinitely often.

Let $y = \sum_{n \geq 1} n^{-1} a_n e_n$. Let $T = x \otimes y^* - y \otimes x^*$. Show that

$$\begin{bmatrix} 0 & T \\ 0 & 0 \end{bmatrix}$$

is a rank two operator in $A$ which is not a finite linear combination of rank one operators.

(iii) Show that the span of the rank one operators of $A$ is weak operator dense in $A$, and in fact, the unit ball is the strong$^*$ closure of this span.

23.8 (Trent) Let $K$ be a closed nowhere dense subset of $[0,1]$ with positive measure.

Let $G = \{(x,x): 0 \leq x \leq 1\} \cup \{(x,y): 0 \leq x \leq \frac{1}{2} \leq y \leq 1, y-x \in K\}$.

Show that $G$ is the graph of a partial order $\leq$, and $m^2(G) > 0$. Hence deduce that $Alg(\{[0,1] \leq, m\})$ contains $C_2$ operators. Show that $G$ does not contain any Borel rectangle. Hence deduce that the algebra contains no finite rank operators.

23.9 Prove that the operator $C_\mu$ of Lemma 23.15 belongs to $A_{\text{fin}}(G_E)$. 
24. Failure of the Distance Formula

In Chapter 9, distance formulae are established for nest algebras and for certain von Neumann algebras. These formulae are of critical importance in the proof of the Similarity Theorem and other results. So it is a significant obstruction that such a formula fails for certain CSL algebras. Indeed, there is no nice class of CSL algebras other than the two above which are known to have any distance formula. In this chapter, the counterexamples will be constructed.

A reflexive algebra $\mathcal{A} = \text{Alg} L$ is hyperreflexive if there is a constant $K$ such that for every $T$ in $B (\mathcal{H})$, 

$$d(T, \mathcal{A}) \leq K \sup_{L \in \mathcal{L}} \|P(L\rangle^\perp TP(L)\|.$$ 

Note that for every $A$ in $\mathcal{A}$ and $L$ in $L = \text{Lat} \mathcal{A}$, one has 

$$\|P(L\rangle^\perp TP(L)\| = \|P(L\rangle^\perp (T-A)P(L)\| \leq \|T-A\|.$$ 

Taking the infimum over $A$ in $\mathcal{A}$ and the supremum over $L$ in $\mathcal{L}$ yields 

$$\sup_{L \in \mathcal{L}} \|P(L\rangle^\perp TP(L)\| \leq d(T, \mathcal{A})$$.

Let the left hand quantity be denoted as $\beta_\mathcal{A}(T)$, or just $\beta(T)$ if $\mathcal{A}$ is understood.

Theorem 9.5 shows that equality holds for nest algebras. However, Example 9.7 shows that a constant greater than one is required even for $3 \times 3$ diagonal matrices. This example is the key to the construction of worse examples.

It is more convenient to work with bimodules over a masa rather than algebras. So we define hyperreflexivity for a subspace $S$. Let 

$$\beta_S(T) = \sup_{\|x\| = 1} d(Tx, Sx).$$

Recall from 15.B that $S$ is reflexive if $\beta_S(T) = 0$ implies $T$ belongs to $S$. Let 

$$\kappa(S) = \sup_{T \in S} \frac{d(T, S)}{\beta_S(T)}.$$ 

Say that $S$ is hyperreflexive if $\kappa(S) < \infty$. The reader should verify that if $S$ is a unital algebra, then the two notions of hyperreflexivity coincide (Exercise 24.1). Moreover, one readily constructs an algebra containing a masa from $S$ which is hyperreflexive precisely when $S$ is (Exercise 24.2).
If $S$ is a weak* closed subspace of $B(\mathcal{H})$, let $S_1$ denote its pre-annihilator in $C_1$. Then $S = (S_1)^\perp$ by the Hahn-Banach Theorem. Suppose $S$ and $T$ are two such subspaces of $B(\mathcal{H}_1)$ and $B(\mathcal{H}_2)$ respectively. Let $S \ast T$ denote the subspace of $B(\mathcal{H}_1 \otimes \mathcal{H}_2)$ called the dual product of $S$ and $T$ given by

$$S \ast T = (S_1 \otimes T_1)^\perp$$

$$= \{ A \in B(\mathcal{H} \otimes \mathcal{H}) : tr(A(X \otimes Y)) = 0 \text{ when } X \in S_1, Y \in T_1 \} .$$

These tensor products are spatial, and $S_1 \otimes T_1$ is endowed with the $C_1$ norm in $C_1(\mathcal{H}_1 \otimes \mathcal{H}_2)$. For the moment, we consider the special case $T = D_3$, the diagonal subalgebra of $\mathcal{M}_3$. Then

$$S \ast D_3 = \left\{ \begin{bmatrix} X_1 & S_{12} & S_{13} \\ S_{21} & X_2 & S_{23} \\ S_{31} & S_{32} & X_3 \end{bmatrix} : X_i \in B(\mathcal{H}), S_{ij} \in S \right\} .$$

**24.1 Lemma.** Let $Y, X_1, X_2$ and $X_3$ belong to $B(\mathcal{H})$. Then

$$\left\| \begin{bmatrix} X_1 & Y & Y \\ Y & X_2 & Y \\ Y & Y & X_3 \end{bmatrix} \right\| \geq \frac{3}{2} \| Y \| .$$

**Proof.** First note that permuting the $X_i$'s does not change the norm. Thus, the norm of the operator is at least as great as the average

$$\left\| T \right\| = \left\| \begin{bmatrix} X & Y & Y \\ Y & X & Y \\ Y & Y & X \end{bmatrix} \right\|$$

where $X = (X_1 + X_2 + X_3)/3$. Fix unit vectors $x$ and $y$ in $\mathcal{H}$, and let $P_x$ and $P_y$ be the projections onto $C_x \oplus C_x \oplus C_x$ and $C_y \oplus C_y \oplus C_y$ respectively. Then

$$\left\| T \right\| \geq \left\| P_x TP_y \right\| = \left\| \begin{bmatrix} \alpha & \beta & \beta \\ \beta & \alpha & \beta \\ \beta & \beta & \alpha \end{bmatrix} \right\|$$

where $\alpha = (Xx,y)$ and $\beta = (Yx,y)$. This latter operator is normal because it equals $3\beta Q + (\alpha - \beta)I$ where $Q = \frac{1}{3} \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$ is a rank one projection. This has spectrum $\{ \alpha - \beta, \alpha + 2\beta \}$. Thus its norm is $\max \{ |\alpha - \beta|, |\alpha + 2\beta| \} \geq (3/2)\beta$. Take the supremum over all unit vectors
\( x, y \) to obtain \( \| T \| \geq (3/2)\| Y \| \).

\[ \textbf{24.2 Lemma. Let} \ S \ \text{be a proper reflexive subspace of} \ B (\mathcal{H}) . \ \text{Then} \]
\[ \kappa(S*P_3) \geq (9/8)^4 \kappa(S) . \]

\[ \textbf{Proof. Fix} \ T \ \text{in} \ B (\mathcal{H}) \ \text{and set} \ \tilde{T} = \begin{bmatrix} T & T & T \\ T & T & T \\ T & T & T \end{bmatrix}. \ \text{For each unit vector} \ x \ \text{in} \ \mathcal{H}, \]
\[ d \begin{bmatrix} \tilde{T}x \\ \tilde{T}x \\ \tilde{T}x \end{bmatrix} \leq \frac{1}{\beta(T)} \leq \sqrt{2} \beta(T) . \]

Likewise, this obtains for unit vectors in \( \mathcal{H}^{(0)} \) with one non-zero coordinate. Now, if \( \| x_1 \|^2 + \| x_2 \|^2 = 1, \)
\[ d \begin{bmatrix} x_1 \\ x_2 \\ 0 \end{bmatrix}, \begin{bmatrix} x_1 \\ x_2 \\ 0 \end{bmatrix} \leq d(T(x_1+x_2), Sx_1+Sx_2) \]
\[ \leq d(T(x_1+x_2), S(x_1+x_2)) \leq \| x_1+x_2 \| \beta(T) \leq \sqrt{2} \beta(T) . \]

Finally, if \( x = \begin{bmatrix} x_1 \\ x_2 \\ x_3 \end{bmatrix} \) and all \( x_i \neq 0 \), then \( S*P_3^x = \mathcal{H}^{(0)}. \) So one obtains
\[ \beta(S*P_3^x) \leq \sqrt{2} \beta(T) . \]

On the other hand, \( S*P_3 \) is weak* closed; so there is an operator \( \tilde{S} = (S_d) \) in \( S*P_3 \) such that \( \| T-\tilde{S} \| = d(T, S*P_3) \). Let \( \tilde{S}_\sigma = (S_{\sigma(i)} \circ \sigma) \) for \( \sigma \) any permutation in \( S_3. \) By symmetry, \( \tilde{S}_\sigma \) belongs to \( S*P_3. \) Since \( T = T_\sigma, \)
\[ d(T, S*P_3) = \| T-\tilde{S} \| = \| T-\tilde{S}_\sigma \| \geq \| T-\frac{1}{6} \sum_{\sigma \in S_3} \tilde{S}_\sigma \| \geq d(T, S*P_3) . \]

Thus, \( \tilde{S} \) can be replaced by the operator \( 1/6 \sum \tilde{S}_\sigma \) which has the form
\[ \begin{bmatrix} X & S & S \\ S & X & S \\ S & S & X \end{bmatrix} \] for some \( S \) in \( S \) and \( X \) in \( B (\mathcal{H}) \). Thus, by Lemma 24.1,
\[ ||\bar{T} - \bar{S}|| = \left\| \begin{bmatrix} T - X & T - S \\ T - S & T - X \end{bmatrix} \right\| \geq \frac{3}{2} ||T - S|| \geq \frac{3}{2} d(T, S). \]

Now it follows that
\[
\kappa(S \ast D_3) \leq \sup_{T \in \mathcal{B}(\mathcal{H})} \frac{d(T, S \ast D_3)}{\beta_{S \ast D_3}(T)} \\
\geq \sup_{T \in \mathcal{B}(\mathcal{H})} \frac{3}{2 \sqrt{2}} \frac{d(T, S)}{\beta(T)} = \left( \frac{9}{8} \right)^{\frac{1}{3}} \kappa(S). 
\]

\section{Corollary} \label{corollary}
Let \( S_n \) denote the dual product of \( n \) copies of \( D_3 \). Then \( \kappa(S_n) \geq (9/8)^{n/2} \).

\section{Corollary} \label{corollary2}
There is a CSL algebra which is not hyperreflexive.

\textbf{Proof.} Let \( S_n \) be as above, and set \( S = \bigoplus_{n \geq 1} S_n \) to be the weak* closure of the direct sum. Let \( D = \bigoplus_{n \geq 1} D_{3^n} \) be the diagonal algebra, and note that \( S \) is a \( D \) bimodule. The algebra \( \mathcal{A} \) consisting of all operators of the form \( \begin{bmatrix} D_1 & S \\ 0 & D_2 \end{bmatrix} \) such that \( D_1 \) and \( D_2 \) belong to \( D \) and \( S \) belongs to \( S \) is a weak* closed algebra containing the atomic masa \( D \oplus D \). Hence \( L = \text{Lat} \mathcal{A} \) is an atomic CSL. It is readily apparent that \( \mathcal{A} \) contains the rank one operators of the form \( PKQ \) where \( P, Q \) are rank one projections in \( D \oplus D \) and \( K \) belongs to \( \mathcal{A} \). These are easily seen to span a weak* dense subspace of \( \text{Alg} L \). So \( \mathcal{A} \) is reflexive, and hence is a CSL algebra.

By the easy parts of Exercises \ref{exercise1} and \ref{exercise2},
\[
\kappa(\mathcal{A}) \geq \kappa(S) \geq \sup_{n \geq 1} \kappa(S_n) = \infty.
\]
So \( \mathcal{A} \) is not hyperreflexive.

To widen the class of counterexamples, we show how to embed \( S_n \) into certain CSL algebras. Let \( A_n \) be the \( 3^n \times 3^n \) matrix with \( a_{ij} = 1 \) if \( S_n \) has non-zero \((ij)\) entries, and \( a_{ij} = 0 \) otherwise.

If \( H_1, \ldots, H_k \) are nests on Hilbert spaces \( H_i \), let \( H_1 \otimes \ldots \otimes H_k \) denote the CSL on \( H_1 \otimes \ldots \otimes H_k \) generated by the subspaces \( N_1 \otimes \ldots \otimes N_k \) for \( N_i \) in \( H_i \).
24.5 Lemma. Suppose that $L = \mathcal{H}_1 \otimes \ldots \otimes \mathcal{H}_k$ is the tensor product of $k$ non-trivial nests. Let $A = (a_{ij})$ be a $k \times k$ matrix of 0's and 1's with distinct columns. Then $L''$ contains two sets $\{E_1, \ldots, E_k\}$ and $\{F_1, \ldots, F_k\}$ of pairwise orthogonal, non-zero intervals of $L$ such that

$$E_i(\text{Alg } L)F_j = a_{ij}E_iB(\mathcal{H})F_j \quad 1 \leq i, j \leq k.$$ 

Proof. Since $\mathcal{H}_i$ is a non-trivial nest, there are intervals $E_i^{(0)}, E_i^{(1)}, F_i^{(0)}$ and $F_i^{(1)}$ satisfying the conditions of the lemma for the matrix $\begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix}$. To see this, note that if $\mathcal{H}_i$ can be split into four pairwise orthogonal intervals, one can choose $E_i^{(0)}$ and $F_i^{(0)}$ such that $E_i^{(0)} \prec F_i^{(0)} \prec E_i^{(1)} \prec F_i^{(1)}$. Otherwise, $\mathcal{H}_i$ consists of two or three atoms $A_1 \prec A_2 (\prec A_3)$. So one can take $E_i^{(0)} = F_i^{(0)} = A_1$ and $E_i^{(1)} = F_i^{(1)} = A_2$.

For $1 \leq i \leq k$, define

$$E_i = E_i^{(0)} \otimes \ldots \otimes E_i^{(1)} \otimes E_i^{(0)} \otimes \ldots \otimes E_i^{(0)}$$

and

$$F_j = F_j^{(a_{1j})} \otimes F_j^{(a_{2j})} \otimes \ldots \otimes F_j^{(a_{kj})}.$$ 

The pairwise orthogonality of $\{F_1, \ldots, F_k\}$ follows since the columns of $A$ are distinct. Clearly, $E_i(\text{Alg } L)F_j = a_{ij}E_iB(\mathcal{H})F_j$ as desired. 

24.6 Theorem. Suppose that $\mathcal{H}_i, 1 \leq i \leq 3^a$, are non-trivial nests, and $L'$ is any CSL. Let $L = \mathcal{H}_1 \otimes \ldots \otimes \mathcal{H}_{3^a} \otimes L'$. Then

$$\kappa(\text{Alg } L) \geq (9/8)^{3^a/2}.$$ 

Proof. Let $A_n$ be the $3^a \times 3^a$ matrix of 0's and 1's determining $S_n$. A simple inductive argument shows that the columns of $A$ are distinct. By Lemma 24.5, there are intervals $E_1, \ldots, E_{3^a}$ and $F_1, \ldots, F_{3^a}$ of $L_0 = \mathcal{H}_1 \otimes \ldots \otimes \mathcal{H}_{3^a}$ so that $E_i(\text{Alg } L_0)F_j = a_{ij}E_iB(\mathcal{H}_0)F_j$, where $\mathcal{H}_0 = \mathcal{H}_1 \otimes \ldots \otimes \mathcal{H}_{3^a}$. Choose unit vectors $x_i$ and $y_j$ in the range of $E_i$ and $F_j$, respectively. The rank one partial isometries $U_{ij} = x_i \otimes y_j^*$ belong to $\text{Alg } L_0$ precisely when $a_{ij} = 1$. Let $P$ and $Q$ be the projections onto $\text{span } \{x_i, 1 \leq i \leq 3^a\}$ and $\text{span } \{y_j, 1 \leq j \leq 3^a\}$ respectively. Then $PB(\mathcal{H}_0)Q$ is linearly isometric to $\mathcal{H}_{3^a}$ in such a way that $P(\text{Alg } L_0)Q$ corresponds to $S_n$. The inverse correspondence sends a matrix $T = (t_{ij})$ to the operator

$$\hat{T} = \sum_{i,j=1}^{3^a} t_{ij}U_{ij}.$$ 

Moreover,
\[
d(T, \text{Alg}(L_0)) \geq d(P Tq, \text{PAlg}(L_0)Q) = d(T, S_n) .
\]

Now compute \( \beta_{\text{Alg } L_0}(T) \). Fix a projection \( R \) in \( L_0 \). Let \( J = \{j : R y_j \neq 0\} \) and \( I = \{i : R^\perp x_i \neq 0\} \). Thus \( I \times J = \{(i, j) : R^\perp U_{ij} R \neq 0\} \).

Now if \( a_{ij} = 1 \), then \( U_{ij} \) belongs to \( \text{Alg } L_0 \) whence \( R^\perp U_{ij} R = 0 \). So \( \{a_{ij} : i \in I, j \in J\} \) consists of zeros. Let \( P_I \) be the projection onto \( \text{span} \{x_i : i \in I\} \), and let \( Q_j \) be the projection onto \( \text{span} \{y_j : j \in J\} \). Then
\[
\|R^\perp T R\| = \|R^\perp (P_I T Q J) R\| \leq \|P_I T Q J\| \leq \beta_{S_n}(T) .
\]

Consequently,
\[
\kappa(\text{Alg } L_0) \geq \sup_{T \in M_n} \frac{d(T, \text{Alg } L_0)}{\beta_{\text{Alg } L_0}(T)} \geq \sup_{T \in M_n} \frac{d(T, S_n)}{\beta_{S_n}(T)} = \kappa(S_n) \geq \left(\frac{9}{8}\right)^{n/2} .
\]

Finally, for \( L = L \otimes L' \), consider the operators \( T \otimes I \). Now, \( \text{Alg } L \) is contained in \( \text{Alg } L_0 \otimes B \langle \mathcal{H} \rangle \), so
\[
d(T \otimes I, \text{Alg } L) \geq d(T \otimes I, \text{Alg } L_0 \otimes B \langle \mathcal{H} \rangle) = d(T, \text{Alg } L_0) .
\]

On the other hand, \( L \) is contained in \( L_0 \otimes \mathcal{E} \) where \( \mathcal{E} \) is the \( \sigma \)-complete Boolean algebra generated by \( L' \). A strongly dense subset of \( L_0 \otimes \mathcal{E} \) is given by the projections of the form
\[
R = \sum_{n \geq 1} R_n \otimes E_n
\]
for \( R_n \) in \( L_0 \) and a partition \( \{E_n : n \geq 1\} \) of the identity in \( \mathcal{E} \). As \( \sum_{n \geq 1} E_n = I \),
\[
R^\perp = \sum_{n \geq 1} I \otimes E_n - \sum_{n \geq 1} R_n \otimes E_n = \sum_{n \geq 1} R_n^\perp \otimes E_n .
\]

Hence
\[
\beta_{\text{Alg } L}(T \otimes I) \leq \sup_{R \in L_0 \otimes \mathcal{E}} \|R^\perp (T \otimes I) R\|
= \sup R \sum_{n \geq 1} \|(R_n^\perp \otimes E_n)(T \otimes I) R_n \otimes E_n\|
= \sup R \sum_{n \geq 1} \|(R_n^\perp T R_n) \otimes E_n\|
= \sup_{R \in L_0} \|R^\perp T R\| = \beta_{\text{Alg } L_0}(T) .
\]

Consequently, \( \kappa(\text{Alg } L) \geq \kappa(\text{Alg } L_0) \geq (9/8)^{n/2} . \)
24.7 Corollary. The infinite tensor product of non-trivial nests fails to be hyperreflexive.

We wish to establish a result more general than Lemma 24.2. To do this, a study of \( S_\perp \) is required.

24.8 Proposition. Let \( S \) be a subspace of \( B(\mathcal{H}) \), and let \( R_1 \) denote the set of rank one operators in \( S_\perp \). Then \( \text{ref}(S) = R_1^\perp \). Thus \( S \) is a reflexive subspace if and only if it is weak* closed and \( R_1 \) spans \( S_\perp \).

Proof. Let \( x \otimes y^* \) belong to \( R_1 \). Then for all \( S \) in \( S \),

\[ 0 = \text{tr}(Sx \otimes y^*) = (Sx, y) \ . \]

Thus \( y \) is orthogonal to \( Sx \). If \( T \) belongs to \( \text{ref}(S) \), one has \( Tx \in Sx \). So \( 0 = (Tx, y) = \text{tr}(Tx \otimes y^*) \). Hence \( T \) belongs to \( R_1^\perp \). Conversely, \( x \otimes y^* \) belongs to \( R_1 \) for every \( y \) in \( (Sx)^\perp \). Hence if \( T \) belongs to \( R_1^\perp \), \( 0 = (Tx, y) \) so \( Tx \) belongs to \( Sx \). Thus \( T \) is in \( \text{ref}(S) \). The last statement of the proposition is a consequence of the Hahn-Banach Theorem.

24.9 Theorem. Let \( S \) be a weak* closed subspace of \( B(\mathcal{H}) \). Let \( C \) denote the closed convex hull of the rank one elements in \( b_1(S_\perp) \). Then \( S \) is hyperreflexive if and only if \( r(S) > 0 \), where

\[ r(S) = \sup \{ r : b_1(S_\perp) \subseteq C \} \ . \]

In this case, \( \kappa(S) = r(S)^{-1} \).

Proof. In the previous proof, it is established that \( x \otimes y^* \) belongs to \( R_1 \) if and only if \( y \in (Sx)^\perp \). Thus for \( T \) in \( B(\mathcal{H}) \),

\[ \sup_{C \in \mathcal{C}} |\text{tr}(TC)| = \sup_{x \otimes y^* \in k(R_1)} |\text{tr}(Tx \otimes y^*)| = \sup_{\|x\| = 1} \sup_{\|Sx\| = 1} |(Tx, y)| = \sup_{\|x\| = 1} \|P(Sx)^\perp Tx\| = \sup_{\|x\| = 1} d(Tx, Sx) = \beta_S(T) \ . \]

Also, by the Hahn-Banach Theorem,

\[ d(T, S) = \sup_{C \in k_1(S_\perp)} |\text{tr}(TC)| \ . \]

So if \( C \) contains \( b_1(S_\perp) \), one obtains

\[ \beta_S(T) \geq \sup_{C \in k_1(S_\perp)} |\text{tr}(TC)| \geq r \cdot d(T, S) \ . \]

Thus, \( \kappa(S) \leq r(S)^{-1} \) and \( S \) is hyperreflexive.

Conversely, suppose \( C \) does not contain \( b_1(S_\perp) \) and in particular does not contain a trace class operator \( X \) in \( b_1(S_\perp) \). By the Hahn-Banach separation theorem, there is an operator \( T \) such that
\[ |tr(TX)| > \sup_{C \subseteq C} \Re \ tr(C) = \sup_{C \subseteq C} |tr(TC)| = \beta_2(T) . \]

Hence
\[ d(T, S) \geq r^{-1} |tr(TX)| > r^{-1} \beta_2(T) . \]

Thus, \( \kappa(S) \geq r(S)^{-1} \) and equality is assured. \(
\square
\)

**24.10 Lemma.** Let \( S \subseteq B(\mathcal{H}_1) \) and \( T \subseteq B(\mathcal{H}_2) \) be reflexive subspaces. Then
\[ S \ast T = \text{ref}(S \otimes B(\mathcal{H}_2) + B(\mathcal{H}_1) \otimes T) . \]

**Proof.** By definition,
\[ (S \ast T)^\perp = S_\perp \otimes T^\perp = \text{span} \{ A \otimes B : A \in S_\perp, T \in T^\perp \} . \]

Since \( S_\perp \) and \( T^\perp \) are spanned by rank one operators, it follows that \( S_\perp \otimes T^\perp \) is also spanned by rank one operators. Thus by Proposition 24.8, \( S \ast T \) is reflexive. If \( S \) belongs to \( S \) and \( X \) belongs to \( B(\mathcal{H}_2) \), then
\[ tr((S \otimes X)(A \otimes B)) = tr(SA)tr(XB) = 0 \]
for every elementary tensor \( A \otimes B \) in \( S_\perp \otimes T^\perp \). Hence \( S \otimes X \) belongs to \( S \ast T \). Thus \( S \ast T \) contains \( S \otimes B(\mathcal{H}_2) \), and also \( B(\mathcal{H}_1) \otimes T \) by symmetry.

To prove the lemma, it now suffices to show that if \( x \otimes y^* \) annihilates \( S \otimes B(\mathcal{H}_2) + B(\mathcal{H}_1) \otimes T \), then it belongs to \( S_\perp \otimes T^\perp \). Now \( S \otimes B(\mathcal{H}_2) \) is a \( I \otimes B(\mathcal{H}_2) \) bimodule. Thus the projections onto \( I \otimes B(\mathcal{H}_2)x \) and \( S \otimes B(\mathcal{H}_2)x \) are invariant for \( I \otimes B(\mathcal{H}_2) \), and hence belongs to \( (I \otimes B(\mathcal{H}_2))' = B(\mathcal{H}_1) \otimes I \) by Theorem 15.1. Let them be denoted by \( Q_1 \otimes I \) and \( P_2 \otimes I \) respectively. Then \( P_1 \) is the projection onto \( SQ_1 \mathcal{H}_1 \). Similarly, there are projections \( Q_2 \) and \( P_2 \) so that \( B(\mathcal{H}_1) \otimes Ix = (I \otimes Q_2)\mathcal{H}_1 \), \( P_2 \mathcal{H}_2 = (I \otimes P_2)\mathcal{H}_2 \) and \( B(\mathcal{H}_1) \otimes Tx = (I \otimes P_2)\mathcal{H}_2 \). Consequently,
\[ S \otimes B(\mathcal{H}_2) + B(\mathcal{H}_1) \otimes T x = ((P_1 \otimes I) \vee (I \otimes P_2))\mathcal{H} \]
\[ = (P_1^\perp \otimes P_2^\perp)^\perp \mathcal{H} . \]

Since \( x \otimes y^* \) annihilates \( S \otimes B(\mathcal{H}_2) + B(\mathcal{H}_1) \otimes T \), it follows that \( (P_1^\perp \otimes P_2^\perp)y = y \). On the other hand,
\[ x = (Q_1 \otimes I)x = (I \otimes Q_2)x = (Q_1 \otimes Q_2)x . \]

As \( SQ_1 = P_1SQ_1 \), it follows that \( Q_1C_1(\mathcal{H}_1)P_1 \) is contained in \( S_\perp \). Likewise, \( Q_2C_2(\mathcal{H}_2)P_2 \) is contained in \( T^\perp \). But
\[ C_1(\mathcal{H}_1) \otimes C_2(\mathcal{H}_2) = C_1(\mathcal{H}_1 \otimes \mathcal{H}_2) , \]
whence it follows that \( S_\perp \otimes T^\perp \) contains
\[(Q_1 \otimes Q_2)C_1(\mathcal{X}_1 \otimes \mathcal{X}_2)(P_1^\perp \otimes P_2^\perp) \times \delta_k\ \] 

In particular, \(x \otimes y^*\) belongs to \(S \otimes T\) as desired. This establishes the lemma. \[\square\]

### 24.11 Theorem

Let \(S\) and \(T\) be proper reflexive subspaces of \(B(\mathcal{X}_1)\) and \(B(\mathcal{X}_2)\). Then \(\kappa(S^*T) \geq \kappa(S)\kappa(T)\).

#### Proof

Fix \(A\) in \(B(\mathcal{X}_1)\) and \(B\) in \(B(\mathcal{X}_2)\). Compute

\[
d(A \otimes B, S^*T) = \sup_{f \in \ell_1(S_{\perp} \otimes T_{\perp})} |f(A \otimes B)| \\
\geq \sup_{g \in \ell_1(S_{\perp}), h \in \ell_1(T_{\perp})} \|g \otimes h\| |A \otimes B| \\
= \sup_{g \in \ell_1(S_{\perp})} |g(A)| \sup_{h \in \ell_1(T_{\perp})} |h(B)| \\
d(A, S)d(B, T).
\]

On the other hand, if \(S \in S\) and \(T \in T\) such that \(\|A-S\| = d(A, S)\) and \(\|B-T\| = d(B, T)\), then \(S \otimes B+(A-S) \otimes T\) belongs to \(S^*T\) and

\[
d(A \otimes B, S^*T) \leq \|A \otimes B-(S \otimes B+(A-S) \otimes T)\| \\
= \|A-S\| \|B-T\| = d(A, S)d(B, T).
\]

Let \(x\) be a unit vector in \(\mathcal{X}_1 \otimes \mathcal{X}_2\), and define \(P_1, Q_1, P_2\) and \(Q_2\) as in the previous lemma. Then

\[
d((A \otimes B)x, S^*Tx) = d((A \otimes B)x, (P_1^\perp \otimes P_2^\perp)x) \\
= \|(P_1^\perp \otimes P_2^\perp)(A \otimes B)(Q_1 \otimes Q_2)x\| \\
\leq \|P_1^\perp A Q_1\| \|P_2^\perp B Q_2\| \leq \beta_S(A)\beta_T(B).\]

Consequently, \(\beta_{S^*T}(A \otimes B) \leq \beta_S(A)\beta_T(B).\)

Hence

\[
\kappa(S^*T) \geq \sup_{A \in B(\mathcal{X}_1), B \in B(\mathcal{X}_2)} \frac{d(A \otimes B, S^*T)}{\beta_{S^*T}(A \otimes B)} \\
\geq \sup_{A \in B(\mathcal{X}_1)} \frac{d(A, S)}{\beta_S(A)} \sup_{B \in B(\mathcal{X}_2)} \frac{d(B, T)}{\beta_T(B)} = \kappa(S)\kappa(T). \]
Notes and Remarks.

The usefulness of distance formulae goes back to the results of Arveson and Christensen dealt with in Chapter 9. The term hyperreflexive was coined in the CBMS survey by Arveson [11]; but the notion has existed for some time. Proposition 24.8 and Theorem 24.9 are contained in Larson [3]. The main results of this section, 24.1-24.7, are due to Davidson and Power [1]. The notion of dual product and Theorem 24.11 are due to Larson [5].

Exercises.

24.1 Show that if a subspace $S$ is hyperreflexive, then
\[ \|P(SM^\perp TP(M))\| \leq \kappa(S)d(T,S) \]
for every subspace $M$ and every $T$ in $B(\mathcal{H})$. Hence deduce that the two notions of hyperreflexivity coincide for unital algebras.

24.2 Let $S$ be a bimodule over a masa $\mathcal{M}$. Let $\mathcal{A}$ be the algebra of all operators of the form
\[
\begin{bmatrix}
M_1 & S \\
0 & M_2
\end{bmatrix}
\]
such that $M_1, M_2 \in \mathcal{M}$ and $S \in S$. Show that
\[ \kappa(S) \leq \kappa(\mathcal{A}) \leq \kappa(S) + 2. \]

24.3 Let $S$ be the weak* closure of $\sum_{n \geq 1} \oplus S_n$ where $S_n$ are weak* closed subspaces. Prove that
\[ \sup_{n \geq 1} \kappa(S_n) \leq \kappa(S) \leq \sum_{n \geq 1} \kappa(S_n). \]
Hint: Note that $S$ is contained in $\sum_{n \geq 1} \oplus B(\mathcal{H})$, so Lemma 9.8 is relevant.

24.4 (Davidson-Power) Fix a basis $\{e_n, n \geq 1\}$ and let $S$ consist of all operators with zero diagonal. This is a bimodule over the diagonal algebra $\mathcal{D}$. Construct an algebras $\mathcal{A}$ as in Exercise 24.2. Show that $\kappa(\mathcal{A}) \leq 3$. Show that $\mathcal{A}$ is not finite width.

24.5 (Larson) With the notation of Theorem 24.11, show that
\[ \beta_S(A \otimes B) = \beta_S(A)\beta_B(B). \]

24.6 (Larson) Let $S = \oplus\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}$. Show that $\kappa(S) = 1$ but $\kappa(S*S) \geq (9/8)^{1/4}$.
24.7 (Larson) Let $A_i$ be a proper reflexive subalgebra of $B(\mathcal{H}_i)$, $1 \leq i \leq n$. Let $\mathcal{A}$ be the algebra
\[
\begin{bmatrix}
A_1 \otimes A_2 \otimes \ldots \otimes A_n & A_1 \ast A_2 \ast \ldots \ast A_n \\
0 & A_1 \otimes A_2 \otimes \ldots \otimes A_n
\end{bmatrix}.
\]
Prove that $\mathcal{A}$ is a reflexive algebra with $\kappa(\mathcal{A}) \geq \kappa(A_1)\kappa(A_2)\ldots\kappa(A_n)$.

24.8 (Davidson-Power) Let $L$ be a CSL such that $Alg L$ is not hyperreflexive. Fix $0 < \epsilon < 1/6$, and choose $T$ in $B(\mathcal{H})$ such that $d(T, Alg L) = 1$ and $\beta(T) < \epsilon$. Set $V = I + \frac{1}{2}T$ and $\mathcal{M} = VL$.

(i) Show that $Alg \mathcal{M}$ is similar to $L$.

(ii) Let $\Theta(L) = VL$ be the natural lattice isomorphism of $L$ onto $\mathcal{M}$. Show that $\|\Theta - \text{id}\| < 2\epsilon$.

(iii) Show that if $S$ is any invertible operator such that $SL = M$, then $\|S-I\| \geq \frac{1}{4}$. Hint: Show that $S^{-1}V$ implements the identity automorphism of $L$.

Hence $S^{-1}V$ belongs to $Alg L$.

24.9* Let $P = \{P_n, n \geq 1\}$ where $P_n = \text{span}\{e_1, \ldots, e_n\}$ in $\ell^2 = \text{span}\{e_k, k \geq 1\}$. Let $P \otimes P$ be the CSL in $\ell^2 \otimes \ell^2$ generated by the two nets $P_1 = \{P_n \otimes \ell^2, n \geq 1\}$ and $P_2 = \{\ell^2 \otimes P_n, n \geq 1\}$. Does $Alg(P \otimes P)$ have a distance formula?

24.10* If $S$ and $T$ are hyperreflexive subspaces, is $S \ast T$ hyperreflexive?
25. Open Problems

The purpose of this short chapter is to collect together some of the more important open problems in the area. Most of these deal with CSL algebras. In this subject, we are motivated in large part by the result for nest algebras. The wonted generalizations to arbitrary CSL algebras are usually difficult, and frequently not true in full generality. Thus exploring the fullest extent of these generalizations may lead to a better understanding of the structure of these interesting algebras. Many of these problems have been mentioned earlier in the text or exercises.

We begin with two questions about nest algebras. Let $P$ denote the standard nest $P_n = \text{span} \{ e_k : 0 \leq k \leq n \}$ on an orthonormal basis $\{ e_k, k \geq 0 \}$.

Problem 1. Is $T(P)^{-1}$ connected?

It is surprising that this problem is open even for such a simple nest. It is conjectured by many that the invertibles in $T(P)$ are not connected. The reason is based on an analogy with function theory. The algebra $H^{\infty}$ of bounded analytic functions on the unit disk is a commutative Banach algebra. Hence the connected component of 1 in $(H^{\infty})^{-1}$ is

$$(H^{\infty})^{-1}_0 = \{ e^h : h \in H^{\infty} \}.$$

It is easy to construct invertible functions in $H^{\infty}$ which have an unbounded logarithm, and hence are not connected to 1 in $(H^{\infty})^{-1}$. For example, $h(z) = \frac{2i}{\pi} \log \frac{1+z}{1-z}$ is a conformal map of the disk onto $\{ z : |\text{Re} z | < 1 \}$. Hence $e^h$ is invertible in $H^{\infty}$ but has unbounded logarithm $h$ (or $h+2n\pi i$).

Now the Toeplitz operator $T = T_h$ belongs to $T(P)$ if one takes $H = H^2$ and $e_k = e^{2\pi k i \theta}$ as the standard basis. The algebra $\{ T_f : f \in H^{\infty} \}$ sits inside $T(P)$. The discussion here shows that $T$ is not connected to $I$ through $T(P)^{-1} \cap \{ \text{Toeplitz operators} \}$. It is a candidate for proving disconnect- edness.

Another candidate is obtained using finite dimensional blocks. There exist nilpotent matrices $V_k$ in $M_k$ such that $\lim_{k \to \infty} \| V_k \| = \infty$ and

$$\lim_{k \to \infty} \| V_k - \text{Re} V_k \| = 0.$$ For example, take a Toeplitz operator $T_h$ where $h_k$ is a conformal map of the disk onto the ellipse $\{(x,y) : (x/k)^2 + (ky)^2 < 1 \}$ such that $h_k(0) = 0$. Then $\| T_h \| = k$ and $\| T_h - \text{Re} T_h \| = k^{-1}$. The compression $V_{k,n}$ of $T_h$ to $P_n$ is always nilpotent (strictly upper triangular), $\| V_{k,n} - \text{Re} V_{k,n} \| \leq k^{-1}$, and for sufficiently large $n$, $\| V_{n,k} \| > k - k^{-1}$. 391
Put these nilpotent matrices $V_k$ in upper triangular form. Set $T_k = e^{iV_k}$ which is invertible in $T_k$, the upper triangular matrices in $\mathcal{M}_k$. Then $T = \bigoplus_{k \geq 1} T_k$ is an invertible upper triangular operator. (Indeed, it is ‘almost’ unitary.) Suppose $T_t$ is a rectifiable path connecting $T$ to $I$ (or one can even assume a piecewise linear path). Then the compression $T_k,t$ of $T_t$ to the $k$-th block yields a path from $T_k$ to $I$ with uniform bounds on $\|T_k,t\|$, $\|T_k^{-1}\|$, and on the length of the path. The existence of such paths appears unlikely.

In the finite dimensions, $\mathcal{T}_k^{-1}$ is always connected. If $T \in \mathcal{T}_k^{-1}$, then $T$ is triangular with non-zero diagonal entries $t_{ii}$. As the diagonal invertible $\mathcal{D}_k^{-1}$ are connected (uniformly in $k$), we may assume that $t_{ii} = 1$ for all $1 \leq i \leq n$. Furthermore, the existence of a nice path as above yields a nice path with ones on the diagonal. There are two interesting paths from $T$ to $I$. One is the straight line $T_t = (1-t)T + tI$. This is bounded by $\|T\|$ and short (length $\|T-I\|$). However, the norm $\|T^{-1}\|$ “blows up” as $k$ increases in the example above. Another path, suggested by Vern Paulsen, is the path

$$\mathcal{T}_s = (t_{ij} e^{i \theta_{ij}}, 0 \leq \theta \leq 1).$$

The map taking $T$ to $T_s$ is a homomorphism of $T_k$ into itself, and thus preserves invertibility. It is also the Schur product of $T$ with the positive matrix $S_s = (e^{i \theta_{ij}})$, and hence the map is contractive. Thus $\|\mathcal{T}_s\| \leq \|T\|$ and $\|\mathcal{T}_s^{-1}\| \leq \|T^{-1}\|$. However, the length of this path “blows up” as $k$ increases.

A third approach involves $K$-theory. In the appendix to Chapter 19, we compute $K_0$ of a nest algebra. There is also the $K_1$ group of $\mathcal{T}(\mathcal{N})$ which deals precisely with connected components in $\bigcup_{n \geq 1} \mathcal{M}_n(\mathcal{T}(\mathcal{N}))$ where $A$ in $\mathcal{M}_n(\mathcal{T}(\mathcal{N}))$ is identified with $A \oplus I_{n-m}$ in $\mathcal{M}_n(\mathcal{T}(\mathcal{N}))$. It is not difficult to show that if $K_1(\mathcal{T}(\mathcal{P})) \neq 0$, then $\mathcal{T}(\mathcal{P})^{-1}$ is not connected. However, this group is unknown. If $\mathcal{N}$ is a nest with only infinite dimensional atoms, then $K_1(\mathcal{T}(\mathcal{N})) = 0$. (For example, $\mathcal{N} = \mathbb{R}^{\omega}$ or $\mathcal{N}$ a continuous nest.) Even in these cases, it is not known if $\mathcal{T}(\mathcal{N})^{-1}$ is connected.

**Problem 2.** Is every maximal nest equal to the invariant subspace lattice of a unicellular operator?

This is the subject of the first half of Chapter 21. There are two basic approaches. One is to construct operators from simple ones, which is the approach taking in Chapter 21. The other is to use convolution type integral operators such as the Volterra operator. Let $\mathcal{Q}$ be the canonical nest on $L^2(\mathbb{Q})$. Since all infinite intervals of $\mathcal{Q}$ are essentially the same, it seems futile to try to build a unicellular operator for $\mathcal{Q}$ from smaller pieces. It is a natural test case for Problem 2. On the other hand, the constructive techniques may well work for countable nests.
The remaining problems concern CSL algebras. All lattices \( L \) in this chapter will be commutative subspace lattices.

**Problem 3.** What is the Jacobson radical of \( \text{Alg} L \)?

Ringrose's characterization of the radical of a nest algebra, Theorem 6.7, is the natural place to start. It is not difficult to define analogous ideals \( I_\phi \) in \( \text{Alg} L \) for every \( \phi \in \text{Hom}(L,2) \), which is homeomorphic to the maximal ideal space of \( C^*(L) = C^*\{P(L); L \in L\} \). So each condition 1)-4) of Theorem 6.7 can be reformulated for arbitrary CSL's. Hopenwasser [1] and Hopenwasser-Larson [1] prove that conditions 2), 3) and 4) are equivalent, and imply membership in the radical 1). So the problem becomes: Is \( \text{rad}(\text{Alg} L) = \bigcap \{I_\phi; \phi \in \text{Hom}(L,2)\} \)?

**Problem 4.** Is there a distance formula for \( \text{Alg}(P \otimes P) \)?

In Chapter 9, distance formulae for nests and nice von Neumann algebras are derived. These are crucial for the similarity theory, perturbations, and many other aspects of nest algebras. However, in the last chapter, we saw that the distance formula fails for arbitrary CSL algebras. Because these estimates are so powerful, it is important to decide if some larger class of CSL algebras has a distance formula. For example, is there a distance formula for finite width lattices? The natural test case for width two lattices is \( P \otimes P \), the lattice on \( \ell^2(2N^2) \) generated by \( \{P_n \otimes \ell^2(N^2), n \geq 0\} \) and \( \{\ell^2(N^2) \otimes P_n, n \geq 0\} \). This can be reformulated as a problem about a uniform estimate for the analogous finite dimensional algebras on \( C^* \).

**Problem 5.** Are there examples of close CSL algebras which are not similar? or even not isomorphic?

In Chapter 18, we saw that the distance formulae for nests and type I von Neumann algebras yield the good perturbation results of Lance and Christensen. Even for arbitrary CSL algebras, one has Theorem 18.2 which shows that close algebras have close lattices. However, Davidson and Power [1] use the failure of the distance formula to exhibit similar CSL algebras with close lattices but the similarity is far from the identity. Choi and Christensen [1] have constructed close, order isomorphic \( C^* \)-algebras which are not unitarily equivalent. Bad behaviour even occurs in finite dimensions for arbitrary matrix algebras (Choi-Davidson [1]). Information about perturbation results for CSL algebras should shed some light on their classification under similarity or approximate unitary equivalence.
Problem 6. Classify commutative subspace lattices up to approximate unitary equivalence.

The notion of similarity is not a good one for CSL's since similarity does not preserve orthogonality. If one wishes to study the similarity classes of CSL's, the appropriate class is the set of complete sublattices of \( \sigma \)-complete Boolean algebras of idempotents in \( B(H) \). (See Davidson [7].) The notion of approximate unitary equivalence is better since it preserves the class of CSL's. The Similarity Theorem 13.20 shows that the classification of nests up to approximate unitary equivalence is given by dimension preserving order isomorphisms. On the other hand, Christensen's Theorem 18.12 shows that close abelian von Neumann algebras are unitarily equivalent. Now if CSL's \( L_1 \) and \( L_2 \) are complemented, approximate unitary equivalence yields approximate unitary equivalence of the abelian von Neumann algebras \( \text{span}(L_1) \) and \( \text{span}(L_2) \). By Christensen's Theorem, these lattices are unitarily equivalent. Even the compact perturbations of abelian von Neumann algebras are rigid because of the Johnson-Parrott Theorem 10.12. Arveson [10] develops a perturbation theory for lattices that is valid for certain "homogeneous" lattices which are compact in the strong operator topology (see Theorem 23.12). In particular, he gives a different proof of Andersen's Theorem 13.9.

What we are looking for here is a way of unifying the nest and Boolean algebra theory.

Problem 7. If \( K \cap \text{Alg} \ L \) is weak* dense in \( \text{Alg} \ L \), is \( L \) completely distributive?

The main thrust of Chapter 23 was an analysis of the relationship between the lattice properties of \( L \) and the density of certain ideals of compact operators in \( \text{Alg} \ L \). What is missing is a lattice theoretic condition equivalent to the density of \( K \cap \text{Alg} \ L \). It is possible that the notion of \( \Lambda \)-distributivity is equivalent to complete distributivity in this context, even though it is formally weaker. If not, any counterexample is likely to shed a useful light on the differences.
Problem 8. If $L_1$ and $L_2$ are commuting synthetic lattices, is $L_1 \vee L_2$ synthetic?

The real problem is to find an operator theoretic approach to synthesis. Problem 8 is one of several test questions. One can also ask if $L_1 \cap L_2$ and $L_1 \otimes L_2$ are synthetic. Arveson’s original approach (Chapter 22) to this problem appears to be mired in measure theoretic technicalities. Froelich [1] has shown that there is a very tight connection with spectral synthesis in commutative harmonic analysis (see Notes 22.38). He has shown how certain results in harmonic analysis translate to exhibit interesting phenomena in CSL algebras. An operator theoretic result which implied something new about harmonic analysis would be very interesting.

Problem 9. Does $\text{Alg} L_1 \otimes \text{Alg} L_2 = \text{Alg}(L_1 \otimes L_2)$?

As in Chapter 15, the tensor products here are spatial and act on $\mathcal{H}_1 \otimes \mathcal{H}_2$. The $\text{Alg} L_1 \otimes \text{Alg} L_2$ is the WOT closed algebra generated by the elementary tensors $A_1 \otimes A_2$ where $A_j \in \text{Alg} L_j, 1 \leq j \leq 2$. Similarly, $L_1 \otimes L_2$ is the complete lattice generated by the subspaces $L_1 \otimes L_2$ where $L_j \in L_j, 1 \leq j \leq 2$. Clearly, $A_1 \otimes A_2$ is contained in $\text{Alg}(L_1 \otimes L_2)$; so the containment

$$\text{Alg} L_1 \otimes \text{Alg} L_2 \subseteq \text{Alg}(L_1 \otimes L_2)$$

is automatic.

If $L_1$ and $L_2$ are complemented, $\mathcal{A}_j = \text{Alg} L_j$ are von Neumann algebras and $L_j$ equals $\text{Proj}(\mathcal{A}_j')$. So the answer to our question in this context becomes a celebrated theorem of Tomita [1]:

$$\mathcal{A}_1 \otimes \mathcal{A}_2 = (\mathcal{A}_1' \otimes \mathcal{A}_2') .$$

If $L_1$ is completely distributive, equality follows from Corollary 23.10 And if $L_1$ is finite width, equality follows from Gilfeather-Hopenwasser-Larson [1]. These three cases suggest that if $L_1$ is synthetic, then equality should hold. Kraus [3] has investigated this problem in even greater generality, and no counter example is known.

Problem 10. Is every contractive representation of a CSL algebra completely contractive?

This is true for weak* continuous representations of nest algebras (Theorem 20.18 and leads to an attractive dilation theory for representations. Paulsen and Power [1] have generalized this to weak* continuous representations of completely distributive lattices. Their methods rely on a nice approximation of $\text{Alg} L$ by tractable finite dimensional subspaces. This kind of approximation may well break down for non-synthetic lattices.
When weak* continuity is dropped, the problem is open even for nest algebras. In particular, one could consider representations of a nest algebra which annihilate the compact operators.

*Note.* The content of this chapter was the subject of a talk by the author at the GPO'TS meeting in Lawrence, KA. A survey article on these same problems, Davidson [11], appears in the proceedings of that conference.

of scalar plus M"acaev class, 182
Finite rank operators,
in CSL algebras, 372
in nest algebras, 35, 37

Generators,
for the Volterra nest algebra, 61
of $M_{\mathfrak{M}}(L)$, 355
of $T(M)$ as an algebra, 204
of $T(M)$ as left ideal, 206
of $T(M)$ bimodules, 202

Hausdorff distance, 255
Hilbert-Schmidt operators, 11
in CSL algebras, 352, 357
hull class, 87
Hyperintransitive, 165
Hyperreflexive, 379

Ideals,
$C_p$, 11
M"acaev, 46
of $B(M)$, 11, 13
of $T(M)$, weak* closed, 202
radical, 68
$K^\infty(M)$, 99, 170

Inner automorphism, 243
of $Q^T(M)$, 247
of $T(M)$, 244
inner operator, 182
Interval, 28
test, 67
invariant mean, 95
Invariant operator range,
of a $C^*$-algebra, 211
of a nest algebra, 213
Invariant subspaces,
of a compact operator, 31, 39
of the Volterra operator, 57
Isomorphism,
of algebras containing $K$, 238
of CSL algebras, 236
of masa, 234
of nest algebras, 241, 243
of quasitriangular algebras, 239

Johnson-Parrott Theorem, 122
join irreducible, 376

$L$-summand, 125
Lattice,
attainable, 317
completely distributive, 363
distributive, 363
finite width, 352
infinitely distributive, 377
of an algebra, 25
of an operator, 23
of operator ranges, 208
splitting property, 364
synthetic, 352
Lidskii's Theorem, 38, 221
Lifting Theorem,
for operators, 293
for nest algebras, 307

$M$-ideal, 125
of a $C^*$-algebra, 127
marginally null, 344
Maximal ideal space of $C^*(M)$, 65
Nest,
  atomic, 25
  approximately unitarily equivalent, 141
  compactly perturbed, 141, 147
  continuous, 25
  finite perturbation of, 141
  maximal, 25
  non-atomic part, 168
  of invariant subspaces for
    a compact operator, 32
    similar, 141
  summands of, 157
Nest algebra, 23
  cohomology of, 286
  compact operators in, 37, 220
  derivations of, 270
  distance to, 105, 220
  finite dimensional, 299
  ideals of, 202
  isomorphisms of, 241, 243
  $K_0$ of, 283
  perturbations of, 258
  preannihilator of, 220
  radical of, 70
  representations of, 299
  unitary orbit of, 325

operator range, 207
Order,
  on a nest, 27
  topology, 27, 65
  ordinal sum, 318
Outer automorphism, 243
  of $T(M)$, 244
  of $Q^* T(M)$, 249
outer operator, 182

Partition, 33, 99
Parrott's example, 312
Perturbation,
  of a CSL algebra, 256
  of a nest algebra, 258
  of abelian von Neumann algebras, 262
Phillip's Lemma, 275, 286
Preannihilator of $T(M)$, 220

Pseudovariable
  of $B(M)$, 19
  of $C_0$, 17
  proximinal, 126
  pseudo integral operator, 343
  pseudo measure, 374

Quasi-central approximate identity, 159
quasitriangular algebra, 137
  characterization of, 139
  distance to, 140
  equality of, 142
quasitriangular operator, 137, 325

Radical,
  Jacobson, 68
  characterization, 70
Rank one operators, 11
  algebraic characterization, 237
  in CSL algebras, 366
  in nest algebras, 34, 240
  reflexive algebra, 25
  reflexive lattice, 25
  reflexive subspace, 197
Reflexivity,
  of a nest, 25
  of a nest algebra, 201
Representation,
  topologically irreducible, 72
  of a nest algebra, 209
Ringrose condition, 70
Ringrose's Theorem, 32

s-number, 11
Schatten p-class, 11
  semidiscreteness,
    for nest algebras, 301
    for von Neumann algebras, 101
semi ideal, 304
  semi simple, 68, 70
  similarity of nests, 141
    continuous, 154
    characterization of, 169
Similarity Theorem, 169
  singular, 166
  singular value, 11
Sinespring Dilation Theorem, 258
Sz. Nagy-Foias Lifting Theorem, 293
Tensor product,
of Hilbert spaces, 193, 195
of operator algebras (spatial), 195
Tomita's Commutation Theorem, 195, 395
trace, 12, 37, 221
Triangular integral, 44
Triangular truncation,
in $\mathcal{M}_a$, 41
in $\mathcal{T}(\mathcal{H})$, 43
in $C_\omega$, 45
in $C$, 46, 49
of a rank one operator, 48
of $C_\omega$, 60, 52

unicyclic operator, 317
unitary equivalence,
of nests, 77
invariant, 85
of multiplicity free nests, 85, 88

vector,
cyclic, 26
separating, 26
support of, 157
Voiculescu's Theorem, 326
Volterra operator, 55
characterization of, 57
commutant, 60
eigenvalues, 59
invariant subspaces, 57
von Neumann algebra,
approximately finite (AF), 92
classification of abelian, 82
injunctive, 100
maximal abelian, 79
multiplicity free, 79
semidiscrete, 101
uniform multiplicity, 81
universal enveloping, 117
von Neumann Inequality, 290, 293

Weyl-von Neumann Theorem 89, 326

INDEX OF SYMBOLS

$\alpha -$ $Aut(\mathcal{H})$, 248
$A_{\min}$, 346, 347
$A_{\max}$, 355
$Aut(\mathcal{H})$, 243
$B (\mathcal{H})$, 326
$C^*(\mathcal{H})$, 65
$C_\omega$, 11
$C_\omega$, 46
$C$, 46
$D(\mathcal{H})$, 26
$D_{\mathcal{M}}, 43$
$D_\Phi$, 67
$Hom(\mathcal{H}, 2)$, 65
$Inn(\mathcal{H}), 243$
$J_{\Phi}$, 67
$L_{\mu}, 43$
$M(\mathcal{H}), 145$
$M_{\mu}, 65$
$M^*_{\mu}, 145$
$N_-, N_+, 24, 25$

$\mathcal{H}, \mathcal{H}^*$, 26
$Out(\cdot)$, 243
$Q_T$, 325
$rad(\cdot)$, 68
$R(\cdot)$, 207
$R_{\infty}(\mathcal{H})$, 99
$S \ast T$, 380
$T(\mathcal{H})$, 23
$U_{\mathcal{M}}, 43$
$x_\rightarrow, x_\#, 364$
$x_\star, 376$
$X^*$, 325
$x \otimes y^*$, 11
$\Delta_{\mu}$, 30
$\kappa(\cdot), 379$
$\phi^{(n)}$, 294
$\vee, \land, 24$
$\ll, 145$
$\otimes$, 348
$conv$
