Cuts in QFT

Cutkosky cuts tell us about the monodromy of Feynman integrals.

Cut edges are edges put on shell.

Cuts should separate the graph – don't consider cutting edges that have both ends in the same component after the cut.

But we do care about cutting into more that 2 pieces – anomalous thresholds.

Trees and Cutkosky

To make connections to Vogtmann's Outer Space, we may want to fix a spanning tree in each component.

If we don't fix a tree

These are a familiar kind of cut

These are familiar cuts from graph theory.

Typically a cut is defined by a partition of the vertices. The edges of the cut are the edges with ends in different parts of the partition.

A spanning forest defines a vertex partition and hence a cut.

Cut space

Put an arbitrary orientation on each edge of the graph.

For an ordered bipartition of the vertices form the signed sum of the edges of the cut.

The span of these is the **cut space** of the graph.

Equivalently the cut space is the row space of the signed incidence matrix of the graph.

The cut space is also the dual of the flow space – essentially the space of momentum flows.

Nice bases				

From the signed incidence matrix perspective we see one basis of the cut space is those cuts that detach single vertices. (with one water removed)

Another nice basis is given by choosing a spanning tree and using the cuts defined by each edge of the spanning tree.

Fundamental cycles

The edges of a spanning tree determine cuts.

The edges not in the spanning tree determine fundamental cycles.

Cuts in graph theory ○○○○○● Incidence bialgebra

Cointeraction

If we don't fix a tree

Anomalous thresholds don't live in the cut space

Anomalous thresholds don't live straightforwardly in the cut space.

Consider the triangle graph as an example.

Supports are tricky because they take us outside of linear algebra.

Cuts in graph theory

Incidence bialgebra

Cointeraction

If we don't fix a tree

< □ > < 同 > < 三 > < 三 > < 三 > < ○ < ○ </p>

So what is it then?

So if it isn't linear algebra, what is it?

We are interested in the containment structure of cuts. Furthermore we may wish to mark some edges as uncuttable, so we are looking at an incidence structure. Cuts in graphs in QFT

If we don't fix a tree

Incidence coalgebras

Given a partially ordered set S with partial order \leq define

$$(n) = \{z \in S : x \leq z \leq y\}$$

Then the set of intervals of ${}^{S}_{ij}$ has a coproduct

$$\rho([x,y]) = \sum_{x \le z \le y} [x,z] \otimes [z,y]$$

and with the counit $[x, y] \mapsto \delta_{x,y}$ this gives the **indicence** coalgebra on *S*.

Incidence coalgebra in the cut context

Fix a graph and a spanning tree T of the graph.

We are interested in the incidence coalgebra on E_T . Interpret an interval [A, B] as A defining a cut (into potentially many pieces if A has many elements) and having the edges of $E_T - B$ be uncuttable, or equivalently contracting them.

Cointeracting bialgebras

Perhaps you have heard Loïc Foissy talk recently on cointeracting bialgebras.

Let $(\underline{A}, \underline{m}_{\underline{A}}, \underline{\Delta})$ and $(\underline{B}, \underline{m}_{\underline{B}}, \underline{\delta})$ be bialgebras with a right coaction $\rho : \underline{A} \rightarrow \underline{A} \otimes \underline{B}$ such that the structure maps of A are comodule morphisms, that is

•
$$\rho(1_A) = 1_A \otimes 1_B$$
,
• $\Delta \otimes \operatorname{id}) \circ \rho = m_{1,3,24} \circ (\rho \otimes \rho) \circ \Delta$,
• for $a, b \in A$, $\rho(ab) = \rho(a)\rho(b)$,
• for $a \in A$, $(\epsilon_A \otimes \operatorname{id}) \circ \rho(a) = \epsilon_A(a)1_B$,
Then the two bialgebras are **cointeracting**.
Often $(A, m_A) = (B, m_B)$ and $\rho = \delta$.
• $\rho(1_A) = 1_A \otimes 1_B$,
• $(A \otimes A \otimes B \otimes A \otimes B)$
• $(A \otimes A \otimes A \otimes B)$

For QFT				

We want to use the ρ defined already. What about Δ and m?

For Δ we want the core Hopf algebra, but with a spanning tree fixed. We can implement this via the fundamental cycles.

Subgraphs that are allowed are unions of So core coproduct in tree Fundamental cycles is a coproduct on Epi Epi by subsets.

Cuts in graphs in QFT

Cuts in graph theory

Incidence bialgebra

Cointeraction ○○●○ If we don't fix a tree

For QTF continued

We want the product not to be disjoint union but union within the fixed graph. Core \checkmark infervals \rightarrow set to 0 if cut or contect information However, ρ acts on tree edges and Δ on non-tree edges. Is not consistent.

Put them together on the space of formal symbols

 $B^{[A_1,A_2]}$

where $B \subseteq E_{\Gamma} - E_{T}$, $[A_{1}, A_{2}]$ is an interval in $\mathcal{P}(f(B))$ and $f: E_{\Gamma} - E_{T} \rightarrow \mathcal{P}(E_{T})$ gives the fundamental cycles. $f(e) = (Dreanevtel cycle of T, e) \cap E_{T}$ thuse: B determines he alograph. B $\cup f(B)$ is the edges of he alograph. A, determines at of short.

Result				

Then (Kreimer, Y, 2021, arXiv:2105.05948) these are cointeracting (wtih Δ restricted to the subspace with intervals [\emptyset , A] and ρ restricted to the subspace where no forbidden tadpoles are contracted.)

When we fix a forest, we don't see the cuts on the sub-side of the modified core coproduct.

So the insertion structure works around the cuts rather than building them.

If we don't fix a tree or forest and allow sub-objects across the cut, then we have a different picture $% \left({{{\mathbf{x}}_{i}}} \right)$

If we don't fix a tree ○●○○○

We can build Dyson-Schwinger equation

We can build Dyson-Schwinger equations that interact with the cut non-trivially.

 $X^{\star} = \mathcal{B}_{+}^{-\star} \left(\frac{(X^{\star})^{3}}{X^{-}} (X^{+})^{2} \right) + \mathcal{B}_{+}^{\star} \left(\frac{X^{\star} (X^{\star})^{2} X^{+}}{(X^{-})^{2}} \right)$

We need cuts through corollas in the skeletons that we insert into.

The usual story

The usual story holds:

- the lemma on the coproduct of the Green functions
- the importance of invariant charges
- $\bullet\,$ put the ρ coaction on Green functions into a matrix.

Or count the gluings

Or turn it around and ask a different question. In a renormalization Hopf algebra instead of the core Hopf algebra, with higher order primitives, we then have higher order primitives with cuts too.

Instead of starting with the graph and cutting, what about starting with the parts and gluing? This has connections to Vogtmann's assembly maps, but also asks an enumeration question: how many subdivergence free gluings are there of graphs?

Cuts in graph theory

Incidence bialgebra

Cointeraction

If we don't fix a tree ○○○○●

Subdivergence free gluings to trees

With Xinle (Clair) Dai and Jordan Long (arXiv:2106.07494), we counted how many subdivergence-free gluings of trees there are in certain special cases:
