# Outline

- Local permutation statistics
- Local class functions
- Application to pattern enumeration

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Path Murnaghan-Nakayama Rule

#### Permutation Statistics

**Def:** A *permutation statistic* is a function  $f : \mathfrak{S}_n \to \mathbb{R}$ .

• 
$$exc(w) = \#\{1 \le i \le n : w(i) > i\}$$

•  $\operatorname{inv}(w) = \#\{1 \le i < j \le n : w(i) > w(j)\}$ 

• 
$$\operatorname{des}(w) = \#\{1 \le i \le n-1 : w(i) > w(i+1)\}$$

• maj(w) = 
$$\sum_{w(i)>w(i+1)} i$$

• 
$$cyc(w) =$$
 number of cycles in w

#### Permutation Statistics

**Def:** A *permutation statistic* is a function  $f : \mathfrak{S}_n \to \mathbb{R}$ .

**Intuition:** A statistic  $f : \mathfrak{S}_n \to \mathbb{R}$  is *k*-local if f(w) is determined by the restriction of *w* to *k*-element subsets of [n].

### Partial Permutations

A partial permutation on [n] of size k is a bijection  $S \xrightarrow{\sim} T$ between two size k subsets  $S, T \subseteq [n]$ .

 $\mathfrak{S}_{n,k} = \{ \text{all partial permutations on } [n] \text{ of size } k \}$ 

**Ex:** Inside  $\mathfrak{S}_{5,2}$  we have the "two-line notation"

$$2 \mapsto 5, 3 \mapsto 1 \quad \Leftrightarrow \quad (23, 51).$$

For  $(I, J) \in \mathfrak{S}_{n,k}$  with  $I = (i_1, \dots, i_k)$  and  $J = (j_1, \dots, j_k)$ , the *indicator statistic*  $\mathbf{1}_{I,J} : \mathfrak{S}_n \to \mathbb{R}$  is

$$\mathbf{1}_{I,J}(w) = \begin{cases} 1 & w(i_1) = j_1, \dots, w(i_k) = j_k \\ 0 & \text{otherwise} \end{cases}$$

#### Local Statistics

**Def:** A permutation statistic  $f : \mathfrak{S}_n \to \mathbb{R}$  is *k*-local if there are constants  $c_{I,J} \in \mathbb{R}$  such that

$$f(w) = \sum_{(I,J)\in\mathfrak{S}_{n,k}} c_{I,J}\cdot \mathbf{1}_{I,J}(w) \text{ for all } w\in\mathfrak{S}_n.$$

•  $exc(w) = \#\{1 \le i \le n : w(i) > i\}$  is 1-local.

• 
$$inv(w) = \#\{1 \le i < j \le n : w(i) > w(j)\}$$
 is 2-local.

- $des(w) = \#\{1 \le i \le n-1 : w(i) > w(i+1)\}$  is 2-local.
- maj(w) =  $\sum_{w(i)>w(i+1)} i$  is 2-local.
- cyc(w) = number of cycles in w has no nontrivial locality.

#### Local Statistics: Basic Facts

**Def:** A permutation statistic  $f : \mathfrak{S}_n \to \mathbb{R}$  is *k*-local if there are constants  $c_{I,J} \in \mathbb{R}$  such that

$$f(w) = \sum_{(I,J)\in\mathfrak{S}_{n,k}} c_{I,J}\cdot \mathbf{1}_{I,J}(w) \text{ for all } w\in\mathfrak{S}_n.$$

- The 0-local statistics are constant functions  $\mathfrak{S}_n \to \mathbb{R}$ .
- Any k-local statistic is also (k + 1)-local.
- Any  $f : \mathfrak{S}_n \to \mathbb{R}$  is (n-1)-local.

**Idea:** The locality of a statistic measures its 'degree'.

# Locality = Degree

**Def:** A permutation statistic  $f : \mathfrak{S}_n \to \mathbb{R}$  is *k*-local if there are constants  $c_{I,J} \in \mathbb{R}$  such that

$$f(w) = \sum_{(I,J)\in\mathfrak{S}_{n,k}} c_{I,J}\cdot \mathbf{1}_{I,J}(w) \text{ for all } w\in\mathfrak{S}_n.$$

- ► A linear combination of *k*-local statistics is *k*-local.
- ▶ If  $f : \mathfrak{S}_n \to \mathbb{R}$  is *k*-local and  $g : \mathfrak{S}_n \to \mathbb{R}$  is *ℓ*-local, then

$$(f \cdot g)(w) = f(w) \cdot g(w)$$

is  $(k + \ell)$ -local.

# Locality = Degree

**Def:** A permutation statistic  $f : \mathfrak{S}_n \to \mathbb{R}$  is *k*-local if  $f = \sum_{(I,J) \in \mathfrak{S}_{n,k}} c_{I,J} \cdot \mathbf{1}_{I,J}$ .

Artin-Wedderburn Theorem: We have an isomorphism

$$\Psi: \mathbb{R}[\mathfrak{S}_n] \to \bigoplus_{\lambda \vdash n} \operatorname{End}_{\mathbb{R}}(V^{\lambda})$$

given by  $\Psi : \alpha \mapsto (\alpha : V^{\lambda} \to V^{\lambda})_{\lambda \vdash n}$ .

**Ubiquitous:** [Ellis-Friedgut-Pipel, Even-Zohar, Huang-Guestrin-Guibas, ...]

$$\begin{array}{ll} f \text{ is } k \text{-local} & \Leftrightarrow & \Psi(\sum_{w \in \mathfrak{S}_n} f(w) \cdot w) \text{ supported on} \\ & \{ \lambda \vdash n \, : \, \lambda_1 \geq n-k \}. \end{array}$$

#### Characters are Local Statistics

Artin-Wedderburn Theorem: We have an isomorphism

$$\Psi:\mathbb{R}[\mathfrak{S}_n]\to\bigoplus_{\lambda\vdash n}\operatorname{End}_{\mathbb{R}}(V^\lambda)$$

given by  $\Psi : \alpha \mapsto (\alpha : V^{\lambda} \to V^{\lambda})_{\lambda \vdash n}$ .

**Ubiquitous:** A statistic  $f : \mathfrak{S}_n \to \mathbb{R}$  is k-local if and only if  $\Psi(\sum_{w \in \mathfrak{S}_n} f(w) \cdot w)$  is supported on  $\{\lambda \vdash n : \lambda_1 \ge n - k\}$ .

**Cor:** Given  $\lambda \vdash n$  with  $\lambda_1 \geq n - k$ , the irreducible character

$$\chi^{\lambda}:\mathfrak{S}_n\to\mathbb{R}$$

(日) (日) (日) (日) (日) (日) (日) (日)

is k-local.

#### Vanilla Permutation Patterns

Let 
$$v = [v(1), \dots, v(k)] \in \mathfrak{S}_k$$
 and  $w = [w(1), \dots, w(n)] \in \mathfrak{S}_n$ .

**Def:** Given  $S = \{i_1 < \cdots < i_k\} \subseteq [n]$ , the permutation *w* matches the pattern *v* at *S* if

 $[w(i_1), \ldots, w(i_k)]$  is order-isomorphic to  $[v(1), \ldots, v(k)]$ .

Define  $N_v : \mathfrak{S}_n \to \mathbb{R}$  by

 $N_v(w) := \#\{S \subseteq [n] : w \text{ matches } v \text{ at } S\}.$ 

**Ex:** If v = [2, 1] then  $inv(w) = N_v(w)$ .

### (Bi)Vincular Permutation Patterns

Let 
$$v = [v(1), \ldots, v(k)] \in \mathfrak{S}_k$$
 and  $w = [w(1), \ldots, w(n)] \in \mathfrak{S}_n$ .

**Def:** Given  $S = \{i_1 < \cdots < i_k\} \subseteq [n]$ , and subsets  $A, B \subseteq [k-1]$  the permutation *w* matches the bivincular pattern (v, A, B) at *S* if

- $[w(i_1), \ldots, w(i_k)]$  is order-isomorphic to  $[v(1), \ldots, v(k)]$  and
- for all  $a \in A$ , we have  $i_{a+1} = i_a + 1$  and
- For all b ∈ B, the b<sup>th</sup> and (b + 1)<sup>st</sup> smallest elements of {w(i<sub>1</sub>),...,w(i<sub>k</sub>)} are consecutive.

Define  $N_{v,A,B} : \mathfrak{S}_n \to \mathbb{R}$  by

$$N_{v,A,B}(w) := \#\{S \subseteq [n] : w \text{ matches } (v,A,B) \text{ at } S\}.$$

**Ex:** If 
$$v = [2, 1]$$
,  $A = \{1\}, B = \emptyset$  then  $des(w) = N_{v,A,B}(w)$ .

Weighted (Bi)Vincular Permutation Patterns

Let 
$$v = [v(1), \ldots, v(k)] \in \mathfrak{S}_k$$
 and  $w = [w(1), \ldots, w(n)] \in \mathfrak{S}_n$ 

**Def:** Given subsets  $A, B \subseteq [k-1]$  and polynomials  $f, g \in \mathbb{R}[x_1, \ldots, x_k]$  we define

$$\mathsf{N}^{f,\mathsf{g}}_{\mathsf{v},\mathsf{A},\mathsf{B}}:\mathfrak{S}_n
ightarrow\mathbb{R}$$

by the rule

$$N_{v,A,B}^{f,g}(w) = \sum_{S} f(i_1,\ldots,i_k) \cdot g(w(i_1),\ldots,w(i_k))$$

where  $S = \{i_1 < \cdots < i_k\}$  ranges over all matches of (v, A, B) in w.

**Ex:** If 
$$v = [2, 1]$$
,  $A = \{1\}$ ,  $B = \emptyset$ ,  $f = x_1, g = 1$  then  $maj(w) = N_{v,A,B}^{f,g}(w)$ .

# Pattern Counting is Local

**Def:** If  $\Upsilon = \{(v, A, B, f, g)\}$  is a family of weighted bivincular patterns, let  $N_{\Upsilon} : \mathfrak{S}_n \to \mathbb{R}$  be

$$N_{\Upsilon}(w) := \sum_{(v,A,B,f,g)\in\Upsilon} N_{v,A,B}^{f,g}(w).$$

**Fact:** If the largest pattern v in  $\Upsilon$  has size k, then  $N_{\Upsilon}$  is k-local.

**Goal:** [After Gaetz-Ryba] Study patterns restricted to some cycle type  $K_{\lambda} \subseteq \mathfrak{S}_n$ .

# Pattern Counting is Local

**Def:** If  $\Upsilon = \{(v, A, B, f, g)\}$  is a family of weighted bivincular patterns, let  $N_{\Upsilon} : \mathfrak{S}_n \to \mathbb{R}$  be

$$N_{\Upsilon}(w) := \sum_{(v,A,B,f,g)\in\Upsilon} N_{v,A,B}^{f,g}(w).$$

**Fact:** If the largest pattern v in  $\Upsilon$  has size k, then  $N_{\Upsilon}$  is k-local.

**Goal:** [After Gaetz-Ryba] Study patterns restricted to some cycle type  $K_{\lambda} \subseteq \mathfrak{S}_n$ .

"That is pure hell." – anonymous senior combinatorialist

### Class Functions and Reynolds

A function  $f : \mathfrak{S}_n \to \mathbb{R}$  is a *class function* if  $f(vwv^{-1}) = f(w)$  for all  $v, w \in \mathfrak{S}_n$ .

**Def:** The *Reynolds operator* R acts on maps  $f : \mathfrak{S}_n \to \mathbb{R}$  by

$$Rf(w) = \frac{1}{n!} \sum_{v \in \mathfrak{S}_n} f(vwv^{-1}).$$

The map  $Rf : \mathfrak{S}_n \to \mathbb{R}$  is a class function.

**Idea:** *Rf* is the *best class function approximation* to *f*.

### Pattern Counting and Reynolds

Let  $\Upsilon$  be a set of weighted bivincular patterns (v, A, B, f, g).

- Let k be the largest size |v| of a pattern v with  $(v, A, B, f, g) \in \Upsilon$ .
- ▶ Let q be the largest size of |A| + |B| for  $(v, A, B, f, g) \in \Upsilon$ .
- Let p be the largest value of |v| − |A| − |B| + deg f + deg g for (v, A, B, f, g) ∈ Υ.

Let  $m_i(w)$  = number of *i*-cycles in *w*.

**Thm:** [HR] For any  $d \ge 0$ , the statistic  $RN^d_{\Upsilon}$  on  $\mathfrak{S}_n$  is a rational function in  $\mathbb{R}(n, m_1, m_2, \ldots, m_{kd})$ . If deg(n) = 1 and deg $(m_i) = i$  the rational degree of  $RN^d_{\Upsilon}$  is  $\le dp$ . Also, the statistic

$$n(n-1)\cdots(n-dq+1)\cdot RN^d_{\Upsilon}\in \mathbb{R}[n,m_1,m_2,\ldots,m_{kd}]$$

is a polynomial in  $n, m_1, m_2, \ldots, m_{kd}$ .

#### Pattern Counting and Reynolds

**Thm:** [HR] For any  $d \ge 0$ , the statistic  $RN^d_{\Upsilon}$  is a rational function in  $\mathbb{R}(n, m_1, m_2, \ldots, m_{kd})$ . If deg(n) = 1 and deg $(m_i) = i$  the rational degree of  $RN^d_{\Upsilon}$  is  $\le dp$ . Also, the statistic

$$n(n-1)\cdots(n-dq+1)\cdot \mathsf{RN}^d_{\Upsilon}\in\mathbb{R}[n,m_1,m_2,\ldots,m_{kd}]$$

is a polynomial in  $n, m_1, m_2, \ldots, m_{kd}$ .

**Rmk:** Proven in the vanilla case by Gaetz-Ryba (single pattern) and Gaetz-Pierson (multiple patterns). Proof uses *Jones Duality* between  $\mathfrak{S}_n$  and  $\mathcal{P}_r(n)$  acting on  $(\mathbb{C}^n)^{\otimes r}$ . Unclear how to extend their methods to vincular or weighted cases.

#### Proof Idea

**Classical Science:** Understand atoms  $\Rightarrow$  Understand molecules.

$$f = \sum_{(I,J)\in\mathfrak{S}_{n,k}} c_{I,J} \cdot \mathbf{1}_{I,J}$$

Atoms of k-Local Statistics:  $\mathbf{1}_{I,J}$  for  $(I, J) \in \mathfrak{S}_{n,k}$ .

$$Rf = \sum_{(I,J)\in\mathfrak{S}_{n,k}} c_{I,J} \cdot R\,\mathbf{1}_{I,J}$$

Atoms of k-Local Class Fcns:  $R \mathbf{1}_{I,J}$  for  $(I, J) \in \mathfrak{S}_{n,k}$ .

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 - のへぐ

#### Atomic Symmetric Functions

Let  $ch_n : Class(\mathfrak{S}_n) \to \Lambda_n$  be the *Frobenius characteristic* 

$$\operatorname{ch}_n: f \mapsto \frac{1}{n!} \sum_{w \in \mathfrak{S}_n} f(w) \cdot p_{\lambda(w)}$$

where  $\lambda(w) \vdash n$  is the cycle type of w.

**Defn:** If  $(I, J) \in \mathfrak{S}_{n,k}$  is a partial permutation, the *atomic* symmetric function is

$$A_{n,I,J} := n! \cdot \mathrm{ch}_{\mathrm{n}}(R \, \mathbf{1}_{I,J}).$$

**Q:** What is the Schur expansion of  $A_{n,I,J}$ ?

### Characters and Atomic Symmetric Functions

**Defn:** If  $(I, J) \in \mathfrak{S}_{n,k}$  is a partial permutation, the *atomic* symmetric function is  $A_{n,I,J} := n! \cdot ch_n(R \mathbf{1}_{I,J})$ .

**Fact:** If 
$$[I, J] = \sum_{\substack{w \in \mathfrak{S}_n \\ w(I) = J}} w \in \mathbb{R}[\mathfrak{S}_n]$$
, then
$$A_{n,I,J} = \sum_{\lambda \vdash n} \chi^{\lambda}[I, J] \cdot s_{\lambda}$$

where  $\chi^{\lambda} : \mathbb{R}[\mathfrak{S}_n] \to \mathbb{R}$  is the irreducible character.

**Q:** What is the Schur expansion of  $A_{n,I,J}$ ?

### Characters and Atomic Symmetric Functions

**Defn:** If  $(I, J) \in \mathfrak{S}_{n,k}$  is a partial permutation, the *atomic* symmetric function is  $A_{n,I,J} := n! \cdot ch_n(R \mathbf{1}_{I,J})$ .

**Fact:** If 
$$[I, J] = \sum_{\substack{w \in \mathfrak{S}_n \\ w(I) = J}} w \in \mathbb{R}[\mathfrak{S}_n]$$
, then
$$A_{n,I,J} = \sum_{\lambda \vdash n} \chi^{\lambda}[I, J] \cdot s_{\lambda}$$

where  $\chi^{\lambda} : \mathbb{R}[\mathfrak{S}_n] \to \mathbb{R}$  is the irreducible character.

**Q:** What is the Schur expansion of  $A_{n,I,J}$ ?

**Useless A:** Apply the Murnaghan-Nakayama Rule (n - k)! times.

# Path and Cycle Notation

Partial permutations  $(I, J) \in \mathfrak{S}_{n,k}$  decompose into *paths* and *cycles*.

**Fact:**  $A_{n,I,J}$  only depends on the unlabeled graph.

# Path and Cycle Notation

Partial permutations  $(I, J) \in \mathfrak{S}_{n,k}$  decompose into *paths* and *cycles*.

**Fact:** We have a factorization  $A_{n,I,J} = A^{\text{path}} \cdot A^{\text{cycle}}$ . Also,  $A^{\text{cycle}}$  is a *power sum*.

$$A_{15,I,J} = A^{\text{path}} \cdot A^{\text{cycle}} = \vec{p}_{332111} \cdot p_{211}$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

#### Path Power Sums

 $\vec{p}_{332111}$ 

**Def:** For  $\mu \vdash n$ , the *path power sum*  $\vec{p}_{\mu}$  is the atomic symmetric function of a graph with paths of sizes  $\mu_1, \mu_2, \ldots$ .

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

### Path Power Sums

**Def:** For  $\mu \vdash n$ , the *path power sum*  $\vec{p}_{\mu}$  is the atomic symmetric function of a graph with paths of sizes  $\mu_1, \mu_2, \ldots$ .

#### Facts: [HR]

- $\{\vec{p}_{\mu}\}\$  is a basis for the space of symmetric functions.
- $\{\vec{p}_{\mu}\}$  is unitriangular to the power sum basis  $\{p_{\nu}\}$ .

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

### Classical Murnaghan-Nakayama

$$A_{n,I,J} = \vec{p}_{\mu} \cdot p_{\nu}$$

**MN Rule:** For  $\nu \models n$ , we have  $p_{\nu} = \sum_{\lambda \vdash n} \chi_{\nu}^{\lambda} \cdot s_{\lambda}$  where

$$\chi_{\nu}^{\lambda} = \sum_{\substack{\nu - \text{ribbon tableaux } T \\ \text{shape } \lambda}} (-1)^{\text{height}(T)}$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

### Classical Murnaghan-Nakayama

**MN Rule:** For  $\nu \models n$ , we have  $p_{\nu} = \sum_{\lambda \vdash n} \chi_{\nu}^{\lambda} \cdot s_{\lambda}$  where

$$\chi_{\nu}^{\lambda} = \sum_{(-1)^{\text{height}(T)}}$$

 $\nu$ -ribbon tableaux T shape  $\lambda$ 

 $p_{3221}=\cdots+1\cdot s_{431}+\cdots$ 

**Q:** What about the *path* power sum  $\vec{p}_{\mu}$ ?

# Monotonic Ribbon Tilings

MONOTONIC

NOT MONOTONIC

Def: In a monotonic ribbon tiling ...

- the tails of the ribbons lie in distinct columns,
- the tail depth decreases from left to right, and
- each initial union of ribbons forms a partition.

# Path Murnaghan-Nakayama Rule

**Thm:** [HR] For  $\mu \vdash n$ , we have  $\vec{p}_{\mu} = \sum_{\lambda \vdash n} \vec{\chi}^{\lambda}_{\mu} \cdot s_{\lambda}$  where

$$\vec{\chi}^{\lambda}_{\mu} = \operatorname{mult}(\mu)! \cdot \sum_{\substack{\text{monotonic tilings } \tau \text{ of } \lambda \\ \text{ribbons of sizes } \mu}} (-1)^{\operatorname{height}(\tau)}$$

・ロト ・ 理 ト ・ ヨ ト ・ ヨ ト ・ ヨ

where the ribbons are to be added in all possible orders.

# Path Murnaghan-Nakayama Rule

$$\vec{p}_{321} = 6s_6 - 4s_{51} + 2s_{33} + 2s_{411} - s_{321}$$

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ ―臣 … のへで

# Atomic Expansion

**Thm:** [HR] Let  $(I, J) \in \mathfrak{S}_{n,k}$  have path partition  $\mu$  and cycle partition  $\nu$ . Then

$$A_{n,I,J} = \vec{p}_{\mu} \cdot p_{\nu} = \sum_{\substack{\lambda \vdash n \\ \rho \subseteq \lambda}} \vec{\chi}_{\mu}^{\rho} \cdot \chi_{\nu}^{\lambda/\rho} \cdot s_{\lambda}$$

where  $\vec{\chi}^{\rho}_{\mu}$  counts monotonic tilings and  $\chi^{\lambda/\rho}_{\nu}$  counts classical tilings.

- Gives a formula for  $\chi^{\lambda}([w \cdot \mathfrak{S}_r]_+)$  on coset sums in  $\mathfrak{S}_n/\mathfrak{S}_r$ .
- Proves polynomiality results for pattern enumeration on conjugacy classes.
- Has applications to probability.

# **Quasi-Random Permutations**

**Defn:** [Cooper] A sequence  $w^{(n)}$  of permutations in  $\mathfrak{S}_n$  is *quasi-random* if for all patterns v we have

$$rac{N_{v}(w^{(n)})}{\binom{n}{k}}=rac{1}{k!}+o(1) \qquad ext{as } n
ightarrow\infty$$

where |v| = k.

**Thm:** [HR] Let  $\mu_n$  be a sequence of conjugacy-invariant probability distributions on  $\mathfrak{S}_n$  and let  $\Sigma_n \sim \mu_n$ . If

$$\lim_{n\to\infty}\mathbb{P}\left(\frac{m_1(\Sigma_n)}{n}=0\right)=1$$

then  $\Sigma_n$  is quasi-random.

Thanks for listening!!
