

Tutorial on Universal Algebra, Mal'cev Conditions, and Finite Relational Structures: Lecture II

Ross Willard

University of Waterloo, Canada

BLAST 2010

Boulder, June 2010

Recap

- Interpretation relation on varieties gives us \mathcal{L} .
- Sitting inside \mathcal{L} is the \wedge -closed sub-poset $\mathcal{A}\text{LG}_{\text{fin}}$.
- Pp-definability relation on finite structures gives us $\mathcal{R}_{\text{EL}_{\text{fin}}}$.
- $\mathcal{R}_{\text{EL}_{\text{fin}}}$ and $\mathcal{A}\text{LG}_{\text{fin}}$ are anti-isomorphic via $[\mathbf{H}] \mapsto [\text{var}(\text{PolAlg}(\mathbf{H}))]$.
- Mal'cev classes in \mathcal{L} induce filters on $\mathcal{A}\text{LG}_{\text{fin}}$ and ideals on $\mathcal{R}_{\text{EL}_{\text{fin}}}$.

One more set to define:

Convention: henceforth, all mentioned relational structures under consideration have **finite** languages.

Theorem (Hell, Nešetřil, 1990)

Suppose \mathbf{G} is a finite undirected graph (without loops).

- If \mathbf{G} is bipartite, then $\text{CSP}(\mathbf{G})$ is in P .
- Otherwise, $\text{CSP}(\mathbf{G})$ is NP-complete.

What the heck is “ $\text{CSP}(\mathbf{G})$ ”?

Definition

Given a finite relational structure \mathbf{G} with finite language L , the **constraint satisfaction problem with fixed template \mathbf{G}** , written $\text{CSP}(\mathbf{G})$, is the following decision problem:

Input: an arbitrary finite L -structure \mathbf{I} .

Question: does there exist a homomorphism $\mathbf{I} \rightarrow \mathbf{G}$?

Also called the **\mathbf{G} -homomorphism** (or **\mathbf{G} -coloring**) problem.

Some context

- [Classical]: $\text{CSP}(K_2) \equiv$ checking bipartiteness, which is in P .
 $\text{CSP}(K_n) \equiv$ graph n -colorability, which is NP -complete for $n \geq 3$ (Karp).
- **Key fact** [Essentially due to Bulatov & Jeavons, unpubl.]:

If \mathbf{G}, \mathbf{H} are finite structures in finite languages and $\mathbf{G} \prec_{\text{pp}} \mathbf{H}$, then $\text{CSP}(\mathbf{G})$ is no harder than $\text{CSP}(\mathbf{H})$.

Consequences:

- If $\text{CSP}(\mathbf{G})$ is in P [resp. NP -complete], then same is true $\forall \mathbf{H} \in [\mathbf{G}]$.
- $\{[\mathbf{G}] : \text{CSP}(\mathbf{G}) \text{ is in } P\}$ is a down-set in $\mathcal{REL}_{\text{fin}}^\omega$.
- $\{[\mathbf{G}] : \text{CSP}(\mathbf{G}) \text{ is } NP\text{-complete}\}$ is an up-set in $\mathcal{REL}_{\text{fin}}^\omega$.
- In fact:
 - $\{[\mathbf{G}] : \text{CSP}(\mathbf{G}) \text{ is in } P\}$ is an ideal in $(\mathcal{REL}_{\text{fin}}^\omega, \vee)$. (Not hard)

Pictorially:

Hell-Nešetřil theorem: there is **dichotomy** for undirected graphs.

The CSP dichotomy conjecture (Feder, Vardi (1998))

There is general dichotomy. I.e., for every finite relational structure **G** in a finite language, $\text{CSP}(\mathbf{G})$ is either in *P* or is *NP*-complete.

Initial steps towards a proof of the Dichotomy Conjecture

1. Reduction to cores.

Definition

Let \mathbf{G}, \mathbf{H} be finite relational structures in the same language.

- \mathbf{G} is **core** if all of its endomorphisms are automorphisms.
- \mathbf{G} is a **core of \mathbf{H}** if \mathbf{G} is core and is a retract of \mathbf{H} .

Facts:

- Every finite relational structure \mathbf{H} has a core, which is unique up to isomorphism; call it $\text{core}(\mathbf{H})$.
- $\text{CSP}(\mathbf{H}) = \text{CSP}(\text{core}(\mathbf{H}))$.

Hence when testing dichotomy, we need only consider cores.

2. Reduction to the endo-rigid case.

Definition

Let $\mathbf{H} = (H, \{relations\})$ be a relational structure.

- \mathbf{H} is **endo-rigid** if its only endomorphism is id_H .
- $\mathbf{H}^c := (H, \{relations\} \cup \{\{a\} : a \in H\})$. (“ \mathbf{H} with constants”)

Facts:

- Endo-rigid \Rightarrow core.
- \mathbf{H}^c is endo-rigid.

Proposition (Bulatov, Jeavons, Krokhin, 2005)

If \mathbf{H} is core, then $\text{CSP}(\mathbf{H})$ and $\text{CSP}(\mathbf{H}^c)$ have the same difficulty.

Hence when testing general dichotomy, we need only consider structures with constants (equivalently, endo-rigid structures).

The reductions in pictures:

“When testing general dichotomy, we need only consider endo-rigid structures.”

\cup

\therefore To establish general dichotomy, it suffices to establish dichotomy in \mathcal{E} .

Question: Where in \mathcal{E} should the “dividing line” be?

Consider the situation for graphs.

Hell-Nešetřil explained: for a finite graph \mathbf{G} ,

- \mathbf{G} bipartite $\Rightarrow \text{core}(\mathbf{G}) = K_2$ or 1 .
- \mathbf{G} non-bipartite $\Rightarrow \dots [\text{core}(\mathbf{G})^c] = [K_3]$.

Question: Where in \mathcal{E} should the “dividing line” be?

The Algebraic CSP Dichotomy Conjecture (BKJ 2000)

We have dichotomy in \mathcal{E} ; moreover, the “dividing line” separating P from NP -complete is between $\mathcal{E} \setminus \{[K_3]\}$ and $\{[K_3]\}$.

Back to algebra: the **Taylor class** T .

Definition

T = the class of varieties V such that $\exists n \geq 1, \exists$ term $t(x_1, \dots, x_n)$ s.t.

- ① $\forall 1 \leq i \leq n, \exists$ an identity of the form

$$V \models t(\text{vars}, \underset{\substack{\uparrow \\ i}}{x}, \text{vars}) \approx t(\text{vars}, \underset{\substack{\uparrow \\ i}}{y}, \text{vars});$$

- ② $V \models t(x, x, \dots, x) \approx x$. (“ t is idempotent.”)

Jargon: such a term t (witnessing $V \in T$) is called a **Taylor term** for V .

Fact: T forms a filter in \mathcal{L} (and hence is a Mal'cev class).

Theorem (Taylor, 1977)

For any **idempotent** variety V (i.e., all basic operations are idempotent), either $[V] = [\text{SETS}]$ or $V \in T$.

Now suppose \mathbf{H} is a finite endo-rigid structure.

Then every basic operation of $\text{PolAlg}(\mathbf{H})$ is idempotent.

- PROOF: $f \in \text{Pol}(\mathbf{H}) \Rightarrow f(x, x, \dots, x)$ is an endomorphism of \mathbf{H}
 $\Rightarrow f(x, x, \dots, x) \approx x$ (\mathbf{H} is endo-rigid).

Hence $V := \text{var}(\text{PolAlg}(\mathbf{H}))$ is an idempotent variety.

As $[\mathbf{H}] = [K_3]$ in \mathcal{E} iff $[V] = [\text{SETS}]$ in \mathcal{L} , we get

Corollary

Suppose $[\mathbf{H}] \in \mathcal{E}$.

- If $[\mathbf{H}] \neq [K_3]$, then $\text{var}(\text{PolAlg}(\mathbf{H})) \in T$ (i.e., \mathbf{H} has a “Taylor polymorphism”).
- Hence the Algebraic Dichotomy Conjecture is equivalent to
 \mathbf{H} endo-rigid and has a Taylor polymorphism $\Rightarrow \text{CSP}(\mathbf{H}) \in P$.

How close are we to verifying the Algebraic CSP Dichotomy Conjecture?

- Measure progress (i.e., the portion of $\mathcal{E} \setminus \{[K_3]\}$ known to be in P) via its image in \mathcal{L} .
- **Thesis:** progress is “robust” if its image in \mathcal{L} “is” a Mal’cev class.

CM = “congruence modular”

HM = “Hobby-McKenzie”

On $\mathcal{A}_{\text{LG}_{\text{fin}}}$: omit types 1,5

$\text{SD}(\wedge)$ = “congruence meet-semidistributive”

On $\mathcal{A}_{\text{LG}_{\text{fin}}}$: omit types 1,2

T = “Taylor”

On $\mathcal{A}_{\text{LG}_{\text{fin}}}$: omit type 1

Another theme: finding “good” Taylor terms.

Definition

An operation f of arity $k \geq 2$ is called a **WNU** operation if it satisfies

$$f(y, x, x, \dots, x) \approx f(x, y, x, \dots, x) \approx f(x, x, y, \dots, x) \approx \dots$$

and

$$f(x, x, \dots, x) \approx x.$$

Observe: any WNU is a Taylor operation.

Theorem (Maróti, McKenzie, 2008, verifying a conjecture of Valeriote)

Suppose \mathbf{A} is a finite algebra and $V = \text{var}(\mathbf{A})$. If V has a Taylor term, then V has a WNU term.

Definition

An operation f of arity $k \geq 2$ is called a **cyclic** operation if it satisfies

$$f(x_1, x_2, x_3, \dots, x_k) \approx f(x_2, x_3, \dots, x_k, x_1)$$

and

$$f(x, x, \dots, x) \approx x.$$

Observe: any cyclic operation is a WNU, since we can specialize the first identity to get

$$f(y, x, x, \dots, x) \approx f(x, y, x, \dots, x) \approx f(x, x, y, \dots, x) \approx \dots$$

Theorem (Barto, Kozik, 201?)

Suppose \mathbf{A} is a finite algebra and $V = \text{var}(\mathbf{A})$. If V has a Taylor term, then V has a cyclic term. (In fact, has a p -ary cyclic term for every prime $p > |A|$.)

Easy proof of the Hell-Nešetřil theorem, using cyclic terms.
(Due to Barto, Kozik?)

Let $\mathbf{G} = (G, E)$ be a finite graph; assume that it is core and not bipartite.
We must show that $[\mathbf{G}^c] = [K_3]$.

Assume the contrary. Then \mathbf{G}^c (and hence also \mathbf{G}) has a Taylor polymorphism.

So by the Barto-Kozik theorem, \mathbf{G} has a cyclic polymorphism of arity p for every prime $p > |G|$.

\mathbf{G} not bipartite $\Rightarrow \mathbf{G}$ contains an odd cycle, and hence contains cycles of every odd length $> |G|$.

Pick a prime $p > |G|$ and a cycle a_1, a_2, \dots, a_p in \mathbf{G} of length p . That is,

$$(a_1, a_2), (a_2, a_3), \dots, (a_{p-1}, a_p), (a_p, a_1) \in E.$$

Pick a cyclic polymorphism f of \mathbf{G} of arity p .

Observe that if

$$\begin{aligned}\mathbf{u} &= (a_1, a_2, \dots, a_{p-1}, a_p) \\ \mathbf{v} &= (a_2, a_3, \dots, a_p, a_1),\end{aligned}$$

then (\mathbf{u}, \mathbf{v}) is an edge of \mathbf{G}^p .

As f is a homomorphism $\mathbf{G}^p \rightarrow \mathbf{G}$, we get that $(f(\mathbf{u}), f(\mathbf{v}))$ is an edge of \mathbf{G} .

But $f(\mathbf{u}) = f(\mathbf{v})$ because f is cyclic. So $(f(\mathbf{u}), f(\mathbf{v}))$ is a loop.

Contradiction!!

In conclusion:

- Good progress is being made on the CSP Dichotomy Conjecture, with essential help from universal algebra.
- The conjecture is motivating new purely algebraic conjectures, some of which have been recently proved.

Thank you!
